11 DPI	170
11.1 Overview	170
11.2 Features	170
11.3 Functional Description	171
11.3.1 DPI Timing	171
11.3.2 Programmable timing parameters	173
11.3.3 Single Buffer	174
11.3.4 Ping-Pong Buffer	174
11.3.5 Test Mode	175
11.3.6 Input Pixel Format	176
11.3.6.1 YUV422 (Interleaved)	176
11.3.6.2 RGB888	177
11.3.6.3 RGB565	177
11.3.6.4 RGBA8888	178
11.3.6.5 YUV420 (Planar)	179
11.3.7 Programmable Interrupt	180
11.3.8 Use with OSD	181
12 DSI	182
12.1 Overview	182
12.2 Features	182
12.3 Functional Description	183
12.3.1 DSI Protocol Layering	183
12.3.2 Physical Layer	185
12.3.3 Clock Lane	186
12.3.3.1 Low Power Mode (LPM, LP11)	187
12.3.3.2 UltraLow Power Mode (ULPM, LP00)	188
12.3.3.3 High Speed Clock Mode (HSCM, HS0/1)	189

12.3.4	Data Lanes	190
12.3.4.1	HighSpeed Data Transmission (HSDT)	190
12.3.4.2	Bus Turn-Around(BTA)	192
12.3.4.3	Escape Mode	193
12.3.4.4	Low Power Data Transmission (LPDT)	194
12.3.4.5	UltraLow Power State (ULPS)	196
12.3.4.6	Remote Application Reset (RAR)	197
12.3.4.7	Acknowledgement (ACK)	198
12.3.5	Lane Management Layer	199
12.3.6	Protocol Layer	202
12.3.6.1	Short Packet	202
12.3.6.2	Long Packet	203
12.3.6.3	Multiple Packets per Transmission	204
12.3.6.4	Bit Order of Bytes in a Packet	205
12.3.6.5	Byte Order in a Packet	206
12.3.6.6	Packet Header (PH)	207
12.3.6.7	Data Identification (DI)	207
12.3.6.8	Virtual Channel (VC)	207
12.3.6.9	Data Type (DT)	207
12.3.6.10	Packet Data (PD)	209
12.3.6.11	Word Count (WC)	209
12.3.6.12	Error Correction Code (ECC)	209
12.3.6.13	Packet Footer (PF)	211
12.3.7	Application Layer	211
12.3.8	Command Mode	212
12.3.9	Video Mode	212
12.3.9.1	Non-Burst Mode with SYNC Pulses	212
12.3.9.2	Non-Burst Mode with SYNC Events	213
12.3.9.3	Burst Mode	214
12.3.10	Line Buffer	215
12.3.11	Display Data Format	216
12.3.11.1	YUV422(8-bit)	216
12.3.11.2	RGB565	217
12.3.11.3	RGB666(loosely packed)	217
12.3.11.4	RGB888	218
12.3.12	Interrupt	219
12.3.13	DMA	220
12.3.14	Use with OSD	221

System and Memory

1.1 System Architecture

BL808 series chips mainly include wireless and multimedia subsystems.

With one RISC-V 32-bit high-performance CPU and Wi-Fi/BT/Zigbee, the wireless subsystem supports wireless connection and data transmission in multiple ways, creating diversified experience.

With one RISC-V 64-bit ultra-high performance CPU and DVP/CSI/ H264/NPU, the multimedia subsystem can be widely used in AI fields like video surveillance and smart speakers.

BL808 system architecture:

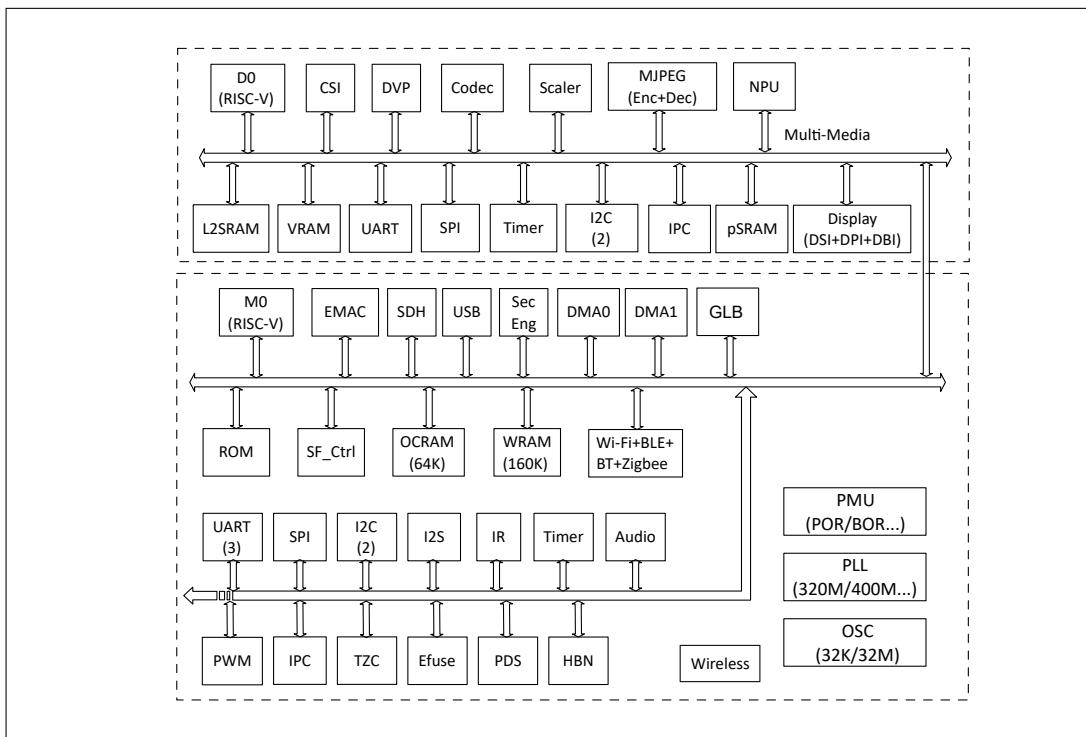

Fig. 1.1: Block Diagram of System

Composition of wireless subsystem:

- CPU
 - One RISC-V high-performance CPU (M0) and one RISC-V low-power CPU (LP)
 - Wireless connection and data transmission in multiple ways, diversified user experience
- Bus interface: AXI and AHB
 - CPU accesses the memory through AXI
 - CPU accesses peripherals through AHB
 - Low power and high performance
- Peripherals
 - Has 30 peripheral modules including UART/SPI/I2C/PWM/SDH/EMAC/USB, allowing connection and storage to and control of peripherals
 - Integrates the Audio module, and supports the input of audio data, analog microphone, and digital microphone, making audio application development easy for users
 - Suits low-power application scenarios, for example, disabling other CPUs and peripherals in low-power scenarios of smart speakers, and using LP for wake-up test of VAD

Composition of multimedia subsystem:

- CPU
 - One RISC-V ultra-high performance CPU (D0)
 - For application fields like video surveillance, smart doorbell, smart cat eye, and smart speaker
 - NPU module for various AI scenarios that accelerates neural network operators
- Peripherals
 - Conventional peripherals like UART/SPI/I2C, facilitating development of system functions
 - CMOS Sensor connected with CSI and DVP interfaces to acquire images and videos; built-in Codec modules for video coding; OSD/Scaler/2DDMA modules for importing video data stream into the Display module

1.2 CPU

BL808 chip contains three RISC-V CPUs, namely M0, D0, and LP. M0 mainly processes network data stream and peripheral access. LP mainly implements some functions in the low-power mode.

1.2.1 M0

1.2.1.1 Features

M0, a 32-bit RISC-V CPU, uses a 5-stage pipeline: fetch, decode, execute, memory access, and write back. This high-performance embedded microprocessor has the following features:

- 32-bit RISC processor
- Supports RISC-V RV32IMAFCP instruction set
- Supports RISC-V 32-bit/16-bit mixed instruction set
- Supports RISC-V machine mode and user mode
- Thirty-two 32-bit integer general purpose registers (GPR) and thirty-two 32-bit/64-bit floating-point GPRs
- Integer (5-stage)/floating-point (7-stage), single-issue, sequentially executed pipeline
- Supports AXI 4.0 main device interface and AHB 5.0 peripheral interface
- 32K instruction cache, two-way set associative structure
- 16K data cache, two-way set associative structure
- Unaligned memory access
- Double-cycle hardware multiplier and Radix-4 hardware divider
- Supports BHT (8K) and BTB
- Supports extended enhanced instruction set
- Supports MCU feature extension technique, including interrupt processing acceleration technique and MCU extension feature
- Compatible with RISC-V CLIC interrupt standard and interrupt nesting; 96 external interrupt sources, 4 bits for configuring interrupt priority
- Compatible with RISC-V PMP, 8 configurable areas
- Supports hardware performance monitor (HPM) units
- Supports RISC-V Debug Specification

1.2.1.2 Extended Functions

- Bit operation instruction, arithmetic operation instruction, and enhanced memory access instruction
- CACHE operation instruction and synchronization instruction, making programming easy for software programmers
- Interrupt speculative push technique and vector interrupt tail-biting technique, accelerated interrupt response, with interrupt response delay of 20 processor clock cycles
- Common application requirements in MCU fields like NMI, low-power mode for deep/light sleep, low-power wake-up events, and locking
- Supports unaligned memory access, which can be enabled/disabled by software, making programming and debugging easy for software programmers

1.2.1.3 Implemented Standards

M0 is compatible with the following RISC-V standards:

- The RISC-V Instruction Set Manual, Volume I: RISC-V User-Level ISA, Version 2.2
- The RISC-V Instruction Set Manual, Volume II: RISC-V Privileged Architecture, Version 1.10
- RISC-V Core-Local Interrupt Controller (CLIC) Version 0.8
- RISC-V External Debug Support Version 0.13.2
- RISC-V “P” Extension Proposal Version 0.9

1.2.2 D0

1.2.2.1 Features

D0 is a 64-bit RISC-V CPU with 5-stage pipeline. This ultra-high performance embedded microprocessor suits fields like security monitoring, intelligent audio processing, and intelligent video processing, and has the following features:

- 64-bit RISC processor
- Supports RISC-V RV64IMAFCV instruction architecture
- Five-stage single-issue sequentially executed pipeline
- Level-1 instruction and data cache of Harvard architecture, with a size of 32 KB and a cache line of 64B
- Sv39 memory management unit, realizing the conversion of virtual and real addresses and memory management
- jTLB that supports 128 entries

- Supports AXI 4.0 128-bit master interface
- Supports core local interrupt (CLINT) and platform-level interrupt controller (PLIC)
- With 80 external interrupt sources, 3 bits for configuring interrupt priority
- Supports BHT (8K) and BTB
- Compatible with RISC-V PMP, 8 configurable areas
- Supports hardware performance monitor (HPM) units

Features of the vector computing unit:

- Compatible with RISC-V V vector extension standard (revision 0.7.1)
- Supports vector execution unit (128 bits)
- Supports INT8/INT16/INT32/FP16/FP32 vector operations
- Supports segment load and store instructions

1.2.2.2 Extended Functions

- Bit operation instruction, arithmetic operation instruction, and enhanced memory access instruction
- CACHE operation instruction and synchronization instruction, making programming easy for software programmers
- Supports unaligned memory access, which can be enabled/disabled by software, making programming and debugging easy for software programmers

1.2.2.3 Implemented Standards

D0 is compatible with the following RISC-V standards:

- The RISC-V Instruction Set Manual, Volume I: RISC-V User-Level ISA, Version 2.2
- The RISC-V Instruction Set Manual, Volume II: RISC-V Privileged Architecture, Version 1.10
- RISC-V “V” Vector Extension, Version 0.7.1-20190610-Workshop-Release.
- RISC-V External Debug Support Version 0.13.2

1.2.3 LP

1.2.3.1 Features

LP, a 32-bit RISC-V CPU, uses a 2-stage pipeline (fetch, decode, execute, and write back), characterized by ultra-low power, ultra-low cost, high code density, and the following features:

- 32-bit RISC processor
- Supports RISC-V RV32EMC instruction set
- Supports RISC-V 32-bit/16-bit mixed instruction set
- Sixteen 32-bit integer GPRs
- Two-stage sequentially executed pipeline
- Supports RISC-V machine mode and user mode
- Compatible with RISC-V CLIC interrupt standard and interrupt nesting, with 32 external interrupt sources
- Supports AHBLite bus protocol, instruction bus, and system bus
- No internal cache
- No PMP
- Supports 2-wire debugging interface

1.2.3.2 Implemented Standards

LP is compatible with the following RISC-V standards:

- The RISC-V Instruction Set Manual, Volume I: RISC-V User-Level ISA, Version 2.2
- The RISC-V Instruction Set Manual, Volume II: RISC-V Privileged Architecture, Version 1.10
- RISC-V Core-Local Interrupt Controller (CLIC) Version 0.8

1.3 Boot

The system supports boot from Flash/UART/USB, as described below:

Table 1.1: Boot mode

Boot Pin	Level	Description
GPIO39	1	Boot from UART (GPIO20/21)/USB for downloading Flash or downloading image to RAM for execution
	0	Boot the application image from Flash

1.4 Address Mapping

Table 1.2: Address mapping

Module	Destination	Start Address	Size	Description
FLASH	FlashA	0x58000000	64MB	Application address space
PSRAM	pSRAM	0x54000000	64MB	pSRAM memory address space
RAM	OCRAM(MCU)	0x22020000	64KB	On Chip RAM address space mainly for M0 application data
	WRAM(MCU)	0x22030000	160KB	Wireless RAM address space mainly for M0 wireless network data
	XRAM(EMI)	0x40000000	16KB	Shared RAM mainly for data communication among M0/LP/D0
	DRAM(MM)	0x3EF80000	512KB	Multimedia-side RAM address space used by D0 application data and modules like H264/NPU
	VRAM(MM)	0x3F000000	32KB	Multimedia-side RAM address space used by D0 application data and modules like H264/NPU

	DMA0	0x2000C000	4KB	DMA0 control register
	I2S	0x2000AB00	256B	I2S control register
	ISO11898 UART2	0x2000AA00	256B	ISO11898 control register
		0x2000AA00	256B	UART2 control register
	I2C1	0x2000A900	256B	I2C1 control register
	IR	0x2000A600	256B	IR control register
	TIMER0	0x2000A500	256B	TIMER0 control register
	PWM	0x2000A400	256B	PWM control register

Table 1.2: Address mapping (continued)

Module	Destination	Start Address	Size	Description
	I2C0	0x2000A300	256B	I2C0 control register
	SPI0	0x2000A200	256B	SPI0 control register
MCUPERI	UART1	0x2000A100	256B	UART1 control register
	UART0	0x2000A000	256B	UART0 control register
	eFuse	0x20056000	4KB	eFuse memory control register
	TZ	0x20005000	4KB	TrustZone control register
	SEC_ENG	0x20004000	4KB	Security engine control register
	GPIP	0x20002000	1KB	General DAC / ADC / ACOMP interface control register
	GLB	0x20000000	4KB	Global control register
ROM	ROM	0x90000000	128KB	Bootrom area address space

1.5 Interrupt Source

CPU_M0 and CPU_LP contain 23 interrupt sources. The interrupt sources and interrupt numbers are shown in the following table:

Table 1.3: Interrupt assignment

Interrupt source		Interrupt Number	Description
DMA	DMA0_ALL	IRQ_NUM_BASE+15	DMA0 ALL Interrupt
	DMA1_ALL	IRQ_NUM_BASE+16	DMA1 ALL Interrupt
IR	IRTX	IRQ_NUM_BASE+19	IR TX Interrupt
	IRRX	IRQ_NUM_BASE+20	IR RX Interrupt
USB	USB	IRQ_NUM_BASE+21	USB Interrupt
EMAC	EMAC	IRQ_NUM_BASE+24	EMAC Interrupt
ADC	GPADC_DMA	IRQ_NUM_BASE+25	GPADC_DMA Interrupt
SPI	SPI0	IRQ_NUM_BASE+27	SPI Interrupt
UART	UART0	IRQ_NUM_BASE+28	UART0 Interrupt
	UART1	IRQ_NUM_BASE+29	UART1 Interrupt
	UART2	IRQ_NUM_BASE+30	UART2 Interrupt
GPIO	GPIO_DMA	IRQ_NUM_BASE+31	GPIO DMA Interrupt
I2C	I2C0	IRQ_NUM_BASE+32	I2C0 Interrupt
	I2C1	IRQ_NUM_BASE+39	I2C1 Interrupt
PWM	PWM	IRQ_NUM_BASE+33	PWM Interrupt
	TIMER0_CH0	IRQ_NUM_BASE+36	Timer0 Channel 0 Interrupt

TIMER0

Table 1.3: Interrupt assignment (continued)

Interrupt source		Interrupt Number	Description
	TIMER0_CH1	IRQ_NUM_BASE+37	Timer0 Channel 1 Interrupt
	TIMER0_WDT	IRQ_NUM_BASE+38	Timer0 Watch Dog Interrupt
I2S	I2S	IRQ_NUM_BASE+40	I2S Interrupt
GPIO	GPIO_INT0	IRQ_NUM_BASE+44	GPIO Interrupt
PDS	PDS_WAKEUP	IRQ_NUM_BASE+50	PDS Wakeup Interrupt
HBN	HBN_OUT0	IRQ_NUM_BASE+51	Hibernate out 0 Interrupt
	HBN_OUT1	IRQ_NUM_BASE+52	Hibernate out 1 Interrupt

CPU_D0 contains 21 interrupt sources. The interrupt sources and interrupt numbers are shown in the following table:

Table 1.4: Interrupt assignment

Interrupt source		Interrupt Number	Description
UART	UART3	IRQ_NUM_BASE+4	UART3 Interrupt
I2C	I2C2	IRQ_NUM_BASE+5	I2C2 Interrupt
	I2C3	IRQ_NUM_BASE+6	I2C3 Interrupt
SPI	SPI1	IRQ_NUM_BASE+7	SPI1 Interrupt
DMA2	DMA2_INT0	IRQ_NUM_BASE+24	DMA INT0 Interrupt
	DMA2_INT1	IRQ_NUM_BASE+25	DMA INT1 Interrupt
	DMA2_INT2	IRQ_NUM_BASE+26	DMA INT2 Interrupt
	DMA2_INT3	IRQ_NUM_BASE+27	DMA INT3 Interrupt
	DMA2_INT4	IRQ_NUM_BASE+28	DMA INT4 Interrupt
	DMA2_INT5	IRQ_NUM_BASE+29	DMA INT5 Interrupt
	DMA2_INT6	IRQ_NUM_BASE+30	DMA INT6 Interrupt
	DMA2_INT7	IRQ_NUM_BASE+31	DMA INT7 Interrupt
EMAC	EMAC2	IRQ_NUM_BASE+36	EMAC2 Interrupt
DMA2D	DMA2D_INT0	IRQ_NUM_BASE+45	DMA2D INT0 Interrupt
	DMA2D_INT1	IRQ_NUM_BASE+46	DMA2D INT1 Interrupt
PWM	PWM	IRQ_NUM_BASE+48	PWM1 Interrupt
TIMER1	TIMER0_CH0	IRQ_NUM_BASE+61	Timer1 Channel 0 Interrupt
	TIMER0_CH1	IRQ_NUM_BASE+62	Timer1 Channel 1 Interrupt
	TIMER0_WDT	IRQ_NUM_BASE+63	Timer1 Watch Dog Interrupt
AUDIO	AUDIO	IRQ_NUM_BASE+64	Audio Interrupt
PDS	PDS	IRQ_NUM_BASE+66	PDS Interrupt

Note: IRQ_NUM_BASE is 16 and the interrupt number 015 is RISC-V reserved interrupt.

Reset and Clock

2.1 Overview

The clock sources in the chip include XTAL, PLL, and RC. They are sent to each module along with frequency division configuration.

2.2 Reset Management

Table 2.1: Software reset function table 1

2.3 Clock Source

Types:

- XTAL: external crystal oscillator clock, with optional frequencies of 24, 32, 38.4, and 40 MHz depending on system requirements
- XTAL32K: external crystal oscillator clock, with frequency of 32 kHz
- RC32K: RC oscillator clock with frequency of 32 kHz and calibration
- RC32M: RC oscillator clock with frequency of 32 MHz and calibration
- PLL: multiple PLL modules, which can generate several clocks with different frequencies to meet various application scenarios

The clock control unit distributes the clocks from the oscillator to the core and peripheral devices. You can choose the system clock source, dynamic frequency divider, and clock configuration, and use the 32 kHz clock in sleep to achieve low-power clock management.

Peripheral clocks include Flash, UART, I2C, SPI, PWM, IR-remote, ADC, and DAC.

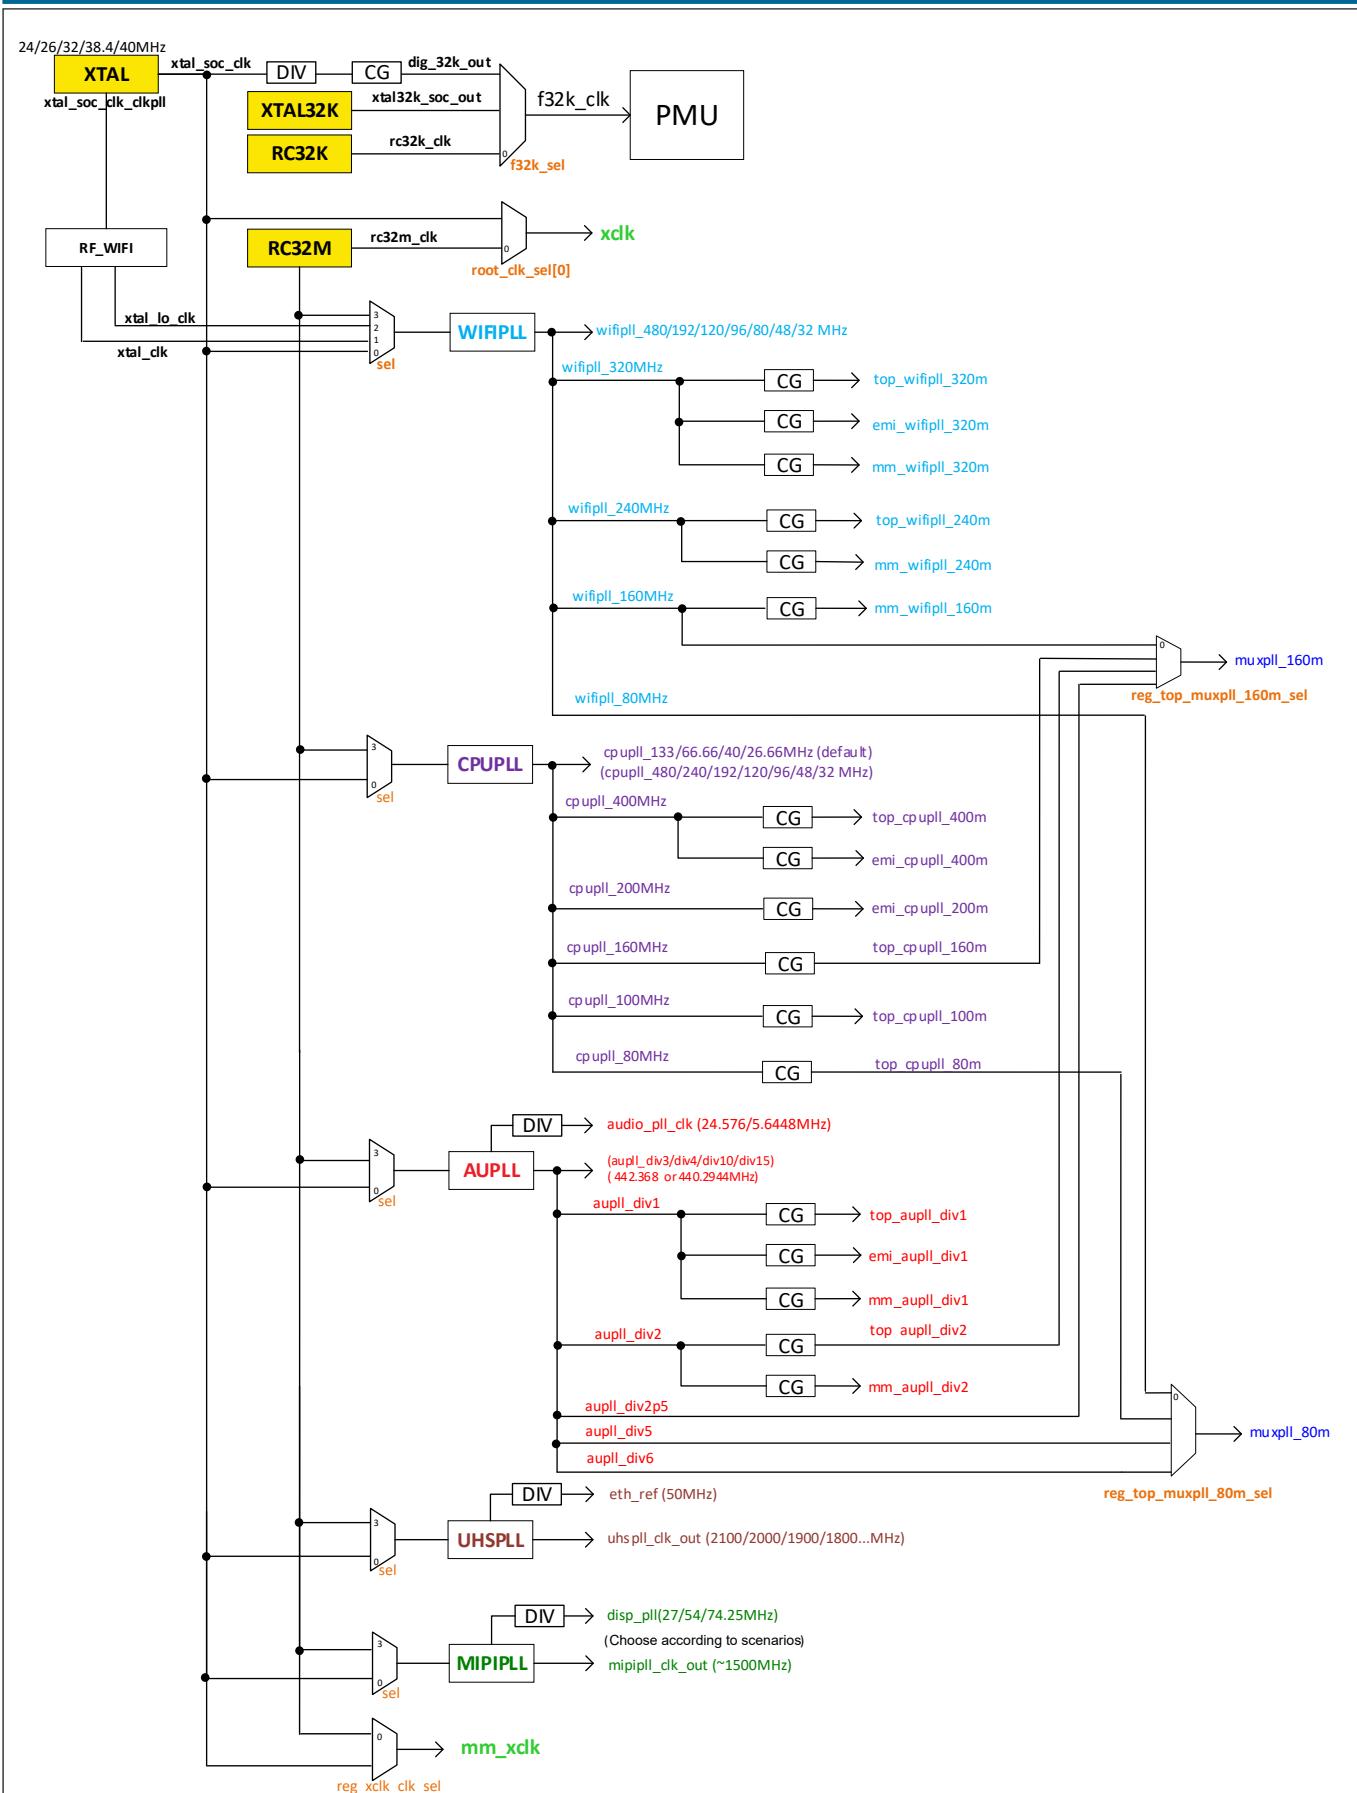

Fig. 2.1: System Clock Architecture

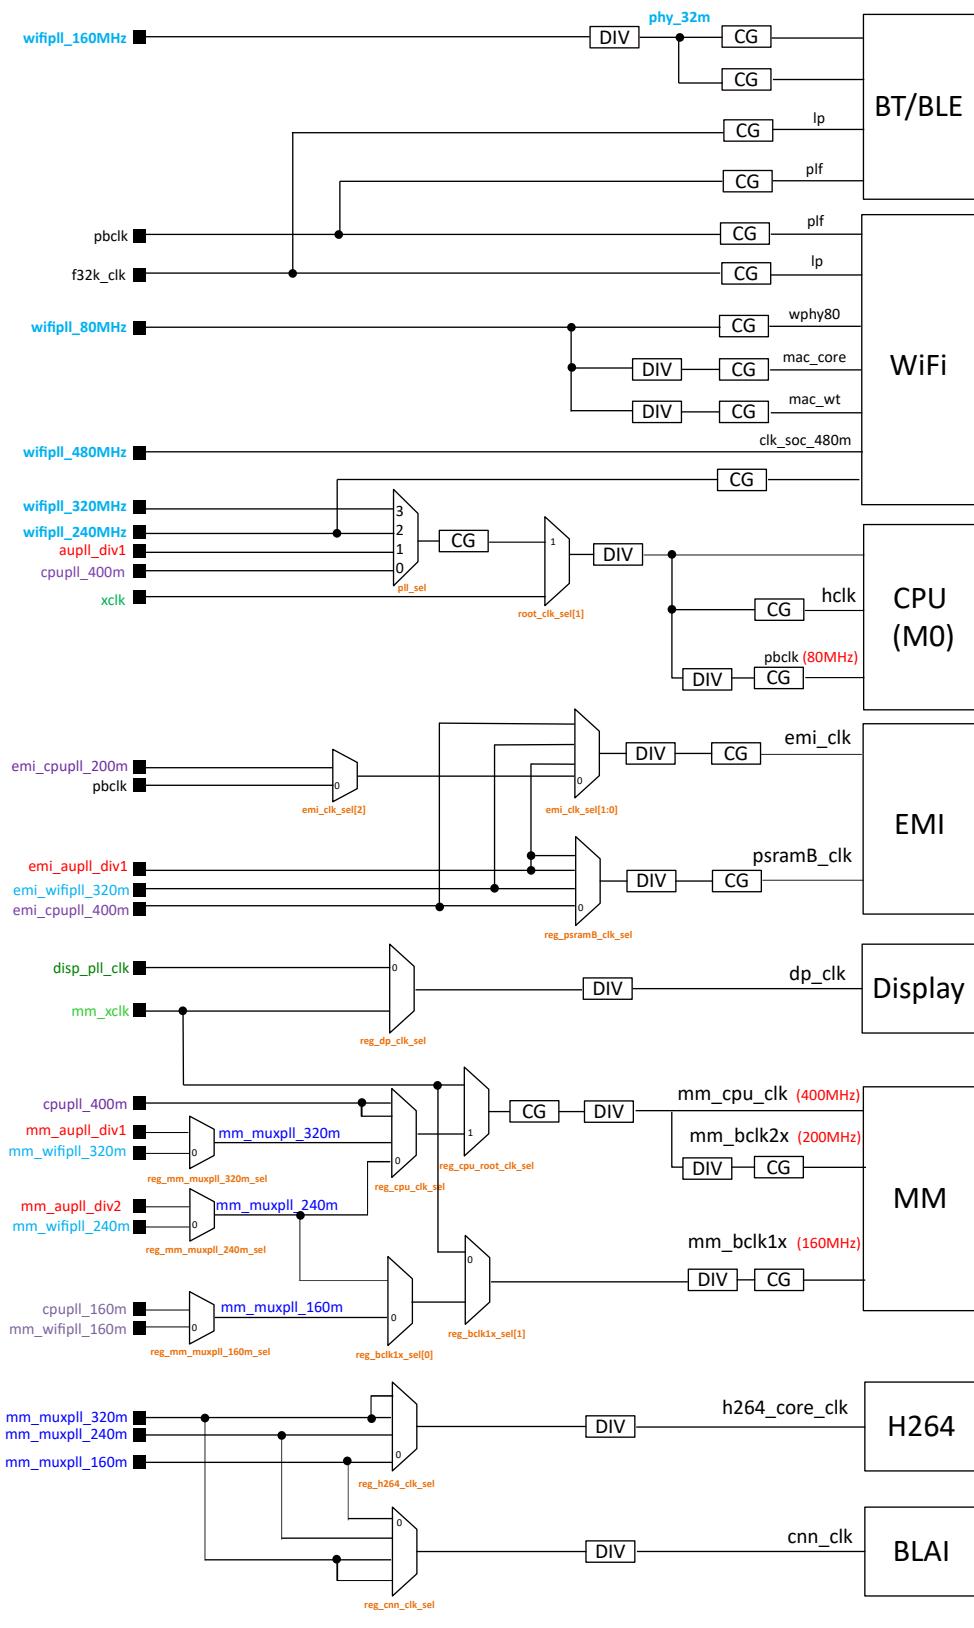

Fig. 2.2: Module Clock Architecture

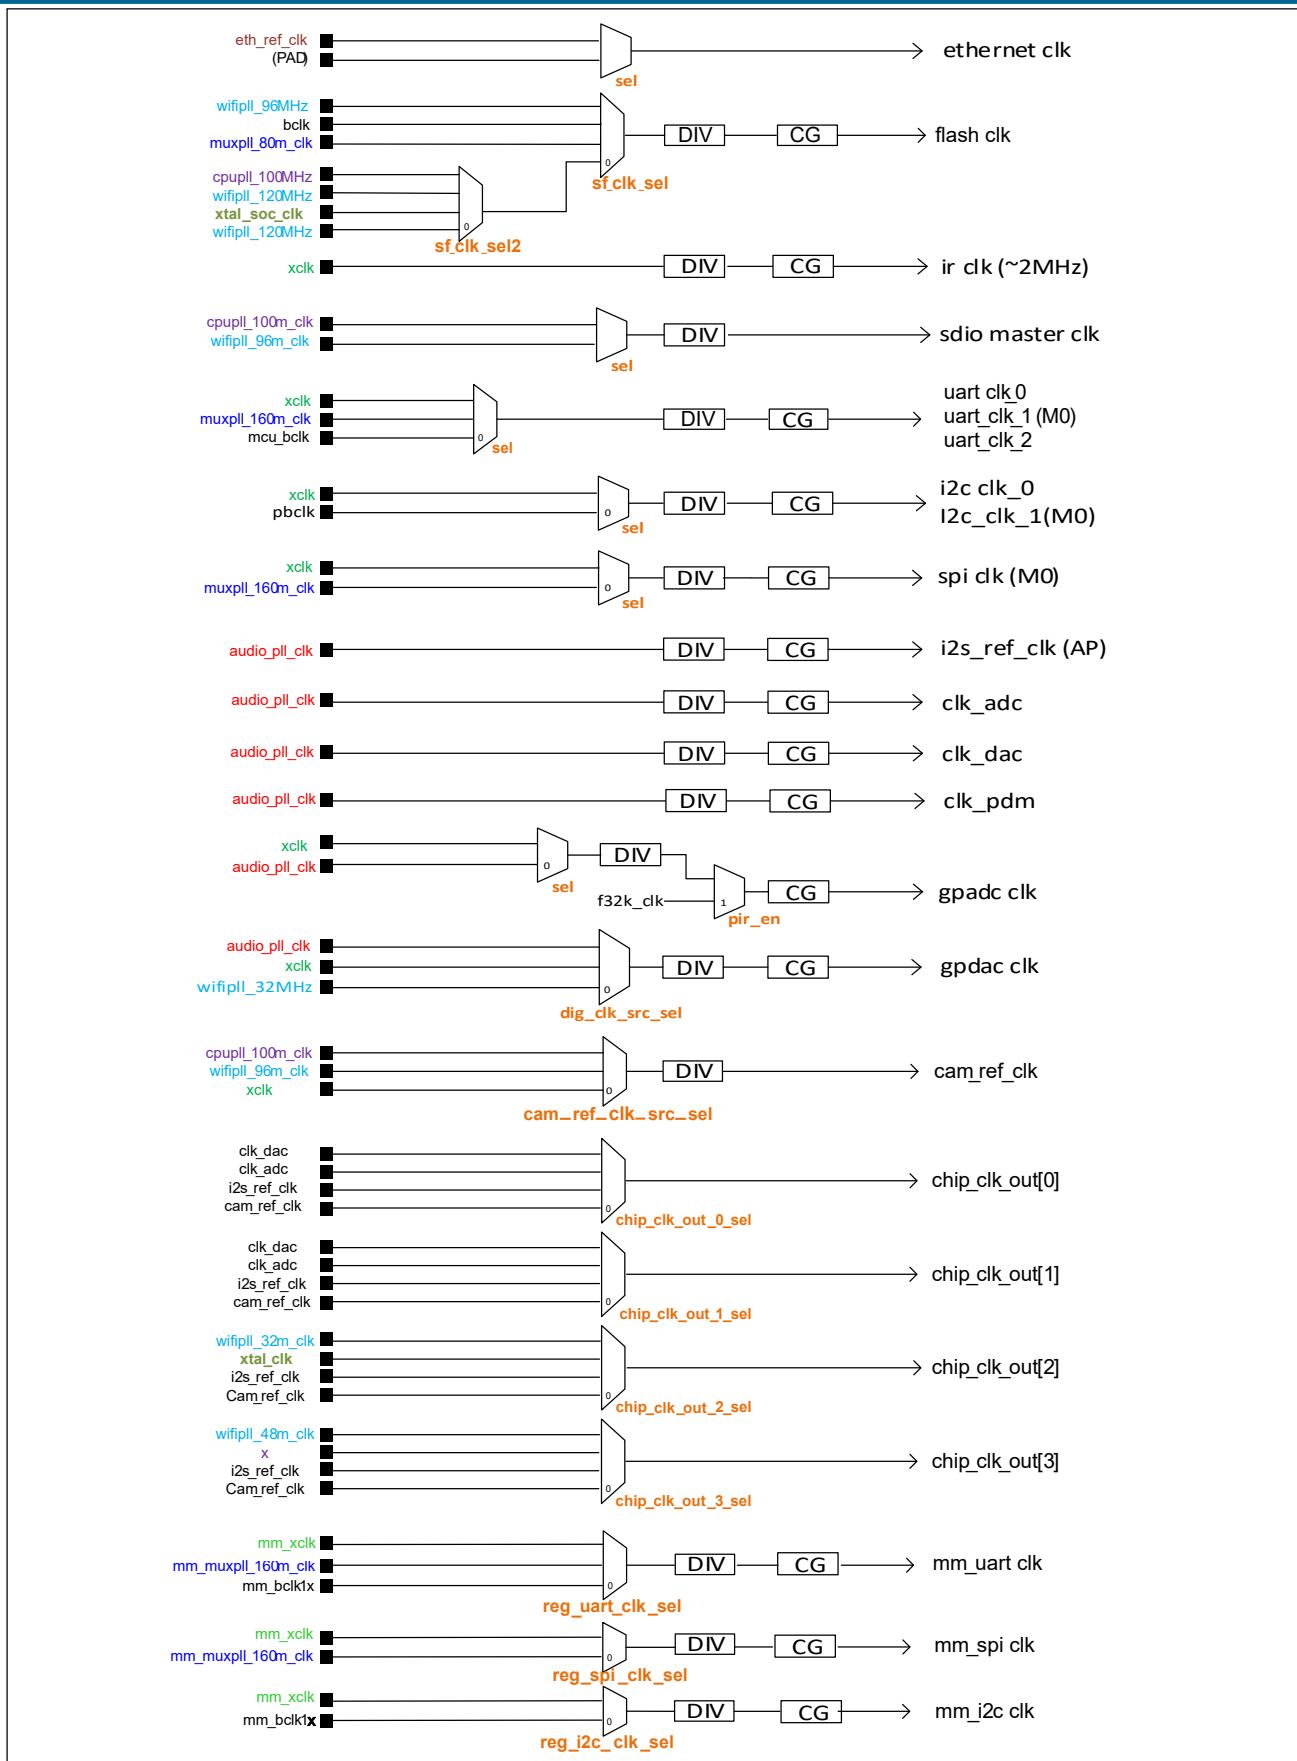

Fig. 2.3: Peripheral Clock Architecture

3.1 Overview

3.2 Functional Description

3.2.1 Clock Management

It is mainly used to set the clocks of processors, buses, and peripherals, set the clock source and frequency division of the above modules, and achieve the clock gating of these modules, to save power for the system. For more details, see system clock sections.

3.2.2 Reset Management

It provides the separate reset function of each peripheral module and the chip reset function.

Chip reset:

- CPU reset: Only CPU is reset. The program will roll back, and peripherals will not be reset
- System reset: All peripherals and CPUs will be reset, but the registers in the AON field will not be reset
- Power-on reset: The whole system including the registers in the AON field will be reset

The application can select a proper reset mode as required.

3.2.3 Bus Management

It provides bus arbitration and bus error settings, so that users can set whether to interrupt and provide the error bus address information when a bus error occurs, facilitating program debugging by users.

3.2.4 Memory Management

It provides power management of each memory module in the low-power mode of the chip system, including two setting modes:

- Retention mode: The data in the memory can be saved, but it cannot be read or written before exiting the low-power mode
- Sleep mode: This mode is only used to reduce system power consumption, because it will cause memory data to lose

4.1 Overview

Users can connect General Purpose I/O Ports (GPIO) with external hardware devices to control these devices.

4.2 Features

- Up to 40 I/O pins
- Each I/O pin supports up to 25 functions
- Each I/O pin can be configured in pull-up, pull-down, or floating mode
- Each I/O pin can be configured as input, output or Hi-Z state mode
- The output mode of each I/O pin has 4 optional drive capabilities
- The input mode of each I/O pin can be set to enable/disable the Schmitt trigger
- Each I/O pin supports 9 external interrupt modes
- FIFO depth: 128 halfwords
- Data can be transferred through DMA from RAM to I/O pins for output

4.3 GPIO Input Settings

Set the register GPIO_CFGxx to configure the general interface to the input mode as described below (xx denotes the GPIO pin number):

- Set `<reg_gpio_xx_ie>` to 1 to enable the GPIO input mode
- Set `<reg_gpio_xx_func_sel>` to 11 to enter the SWGPIO mode
- In the SWGPIO mode, set to enable/disable the Schmitt trigger through `<reg_gpio_xx_smt>` for waveform shaping

- Set to enable/disable the internal pull-up and pull-down functions through <reg_gpio_xx_pu> and <reg_gpio_xx_pd>
- Set the type of external interrupt through <reg_gpio_xx_int_mode_set>, and then read the level value of I/O pin through <reg_gpio_xx_i>

4.4 GPIO Output Settings

The following four output modes of GPIO can be set through the register GPIO_CFGxx.

4.4.1 Normal Output Mode

- Set <reg_gpio_xx_oe> to 1 to enable the GPIO output mode
- Set <reg_gpio_xx_func_sel> to 11 to enter the SWGPIO mode
- Set <reg_gpio_xx_mode> to 0 to enable the normal output function of I/O
- Set to enable/disable the internal pull-up and pull-down functions through <reg_gpio_xx_pu> and <reg_gpio_xx_pd>, and then set the level of I/O pin through <reg_gpio_xx_o>

4.4.2 Set/Clear Output Mode

- Set <reg_gpio_xx_oe> to 1 to enable the GPIO output mode
- Set <reg_gpio_xx_func_sel> to 11 to enter the SWGPIO mode
- Set <reg_gpio_xx_mode> to 1 to enable the Set/Clear output function of I/O
- Set to enable/disable the internal pull-up and pull-down functions through <reg_gpio_xx_pu> and <reg_gpio_xx_pd>

In the Set/Clear output mode, you can set <reg_gpio_xx_set> to 1 to keep the I/O pin at the high level, or set <reg_gpio_xx_clr> to 1 to keep the I/O pin at the low level. If both <reg_gpio_xx_set> and <reg_gpio_xx_clr> are set to 1, the I/O pin is kept at the high level. If both of them are set to 0, the setting does not work.

4.4.3 Buffer Output Mode

- Set <reg_gpio_xx_oe> to 1 to enable the GPIO output mode
- Set <reg_gpio_xx_func_sel> to 11 to enter the SWGPIO mode
- Set <reg_gpio_xx_mode> to 2 to enable the buffer output function of I/O
- Set to enable/disable the internal pull-up and pull-down functions through <reg_gpio_xx_pu> and <reg_gpio_xx_pd>

In the buffer output mode, when the <cr_gpio_tx_en> bit in the register GPIO_CFG142 is set to 1, the data stored in the register GPIO_CFG144 is written into the corresponding I/O pins one by one in order, to set the level of pin. The

size of the buffer area is 128 * 16 bits.

The level state output to the pin can be set freely. With XCLK as the clock source, the value set to <cr_code_total_time> in the register GPIO_CFG142 is one cycle:

Level state of logical ‘1’ : For a high level set by <cr_code1_high_time> plus a low level set by <cr_code_total_time><cr_code1_high_time>, when <cr_invert_code1_high> is 0, logical ‘1’ outputs high level first and then low level, and otherwise, low level first and then high level.

Level state of logical ‘0’ : For a high level set by <cr_code0_high_time> plus a low level set by <cr_code_total_time><cr_code0_high_time>, when <cr_invert_code0_high> is 0, logical ‘0’ outputs high level first and then low level, and otherwise, low level first and then high level.

Note: As the register of the buffer is 16-bit wide, every 16 pins form a group, and the pins with the lowest to highest serial numbers in a group are controlled by the corresponding bits in the buffer. The <cr_gpio_dma_out_sel_latch> bit in the register GPIO_CFG143 shall be set to 0. <cr_gpio_dma_park_value> is used to set the default level of I/O, namely 1 for high level and 0 for low level.

When <cr_code_total_time> = 10, <cr_code0_high_time> = 1, <cr_code1_high_time> = 5, <cr_invert_code0_high> = 0, <cr_invert_code1_high> = 0, <cr_gpio_dma_park_value> = 0, and <cr_gpio_dma_out_sel_latch> = 0, the waveform is shown as follows:

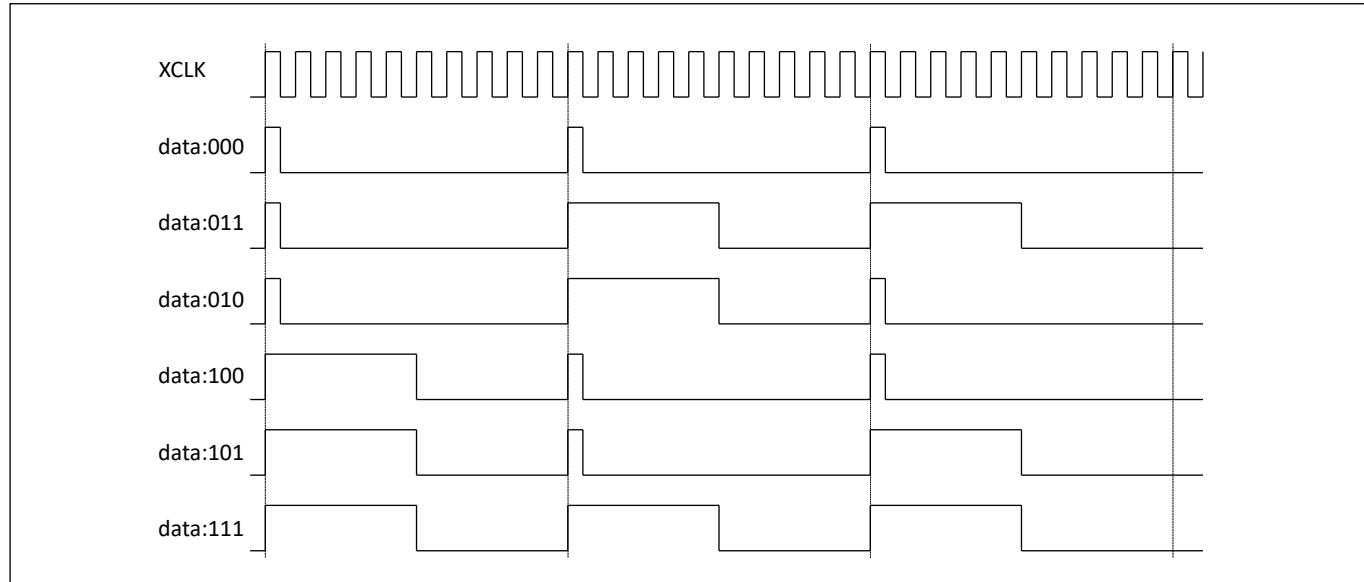

Fig. 4.1: General GPIO Output Waveform

When <cr_code_total_time> = 10, <cr_code0_high_time> = 1, <cr_code1_high_time> = 5, <cr_invert_code0_high> = 0, <cr_invert_code1_high> = 1, <cr_gpio_dma_park_value> = 1, and <cr_gpio_dma_out_sel_latch> = 0, the waveform is shown as follows:

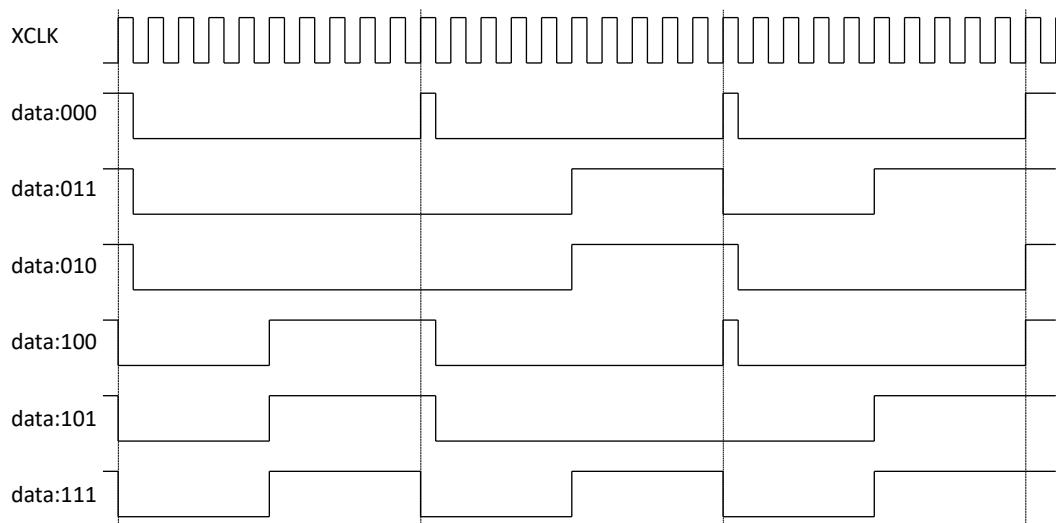

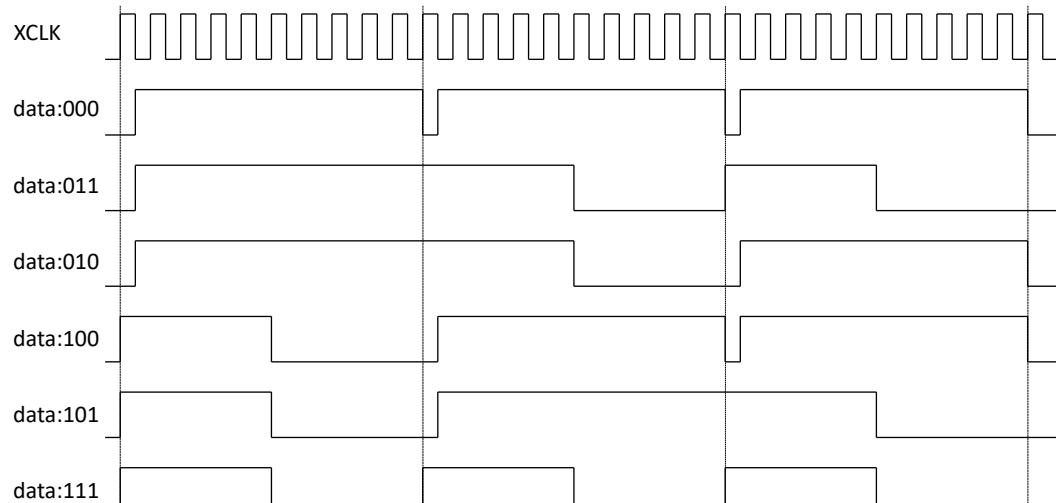

Fig. 4.2: Output Waveform of Inverted Level of Logical ‘1’ in Default High Level

When `<cr_code_total_time>` = 10, `<cr_code0_high_time>` = 1, `<cr_code1_high_time>` = 5, `<cr_invert_code0_high>` = 1, `<cr_invert_code1_high>` = 0, `<cr_gpio_dma_park_value>` = 0, and `<cr_gpio_dma_out_sel_latch>` = 0, the waveform is shown as follows:

configuration: T12 = 10, L0T1 = 1, L1T1 = 5, L0S1 = 1, L1S1 = 0, PS = 0, TM = 0

Example 3 of GPIO output tx configuration

Fig. 4.3: Output Waveform of Inverted Level of Logical ‘0’ in Default Low Level

When `<cr_code_total_time>` = 10, `<cr_code0_high_time>` = 1, `<cr_code1_high_time>` = 5, `<cr_invert_code0_high>` = 1, `<cr_invert_code1_high>` = 1, `<cr_gpio_dma_park_value>` = 1, and `<cr_gpio_dma_out_sel_latch>` = 0, the waveform

is shown as follows:

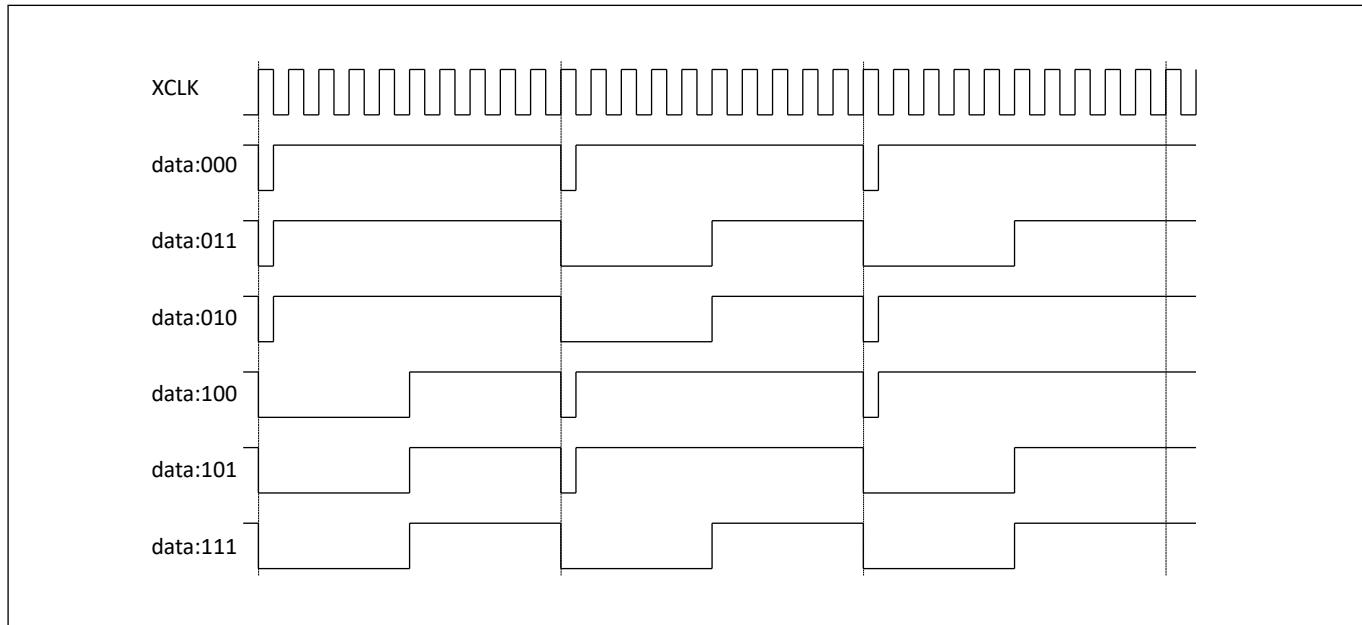

Fig. 4.4: Output Waveforms of Inverted Levels of Logical ‘0’ and Logical ‘1’ in Default High Level

4.4.4 Cache Set/Clear Output Mode

- Set `<reg_gpio_xx_oe>` to 1 to enable the GPIO output mode
- Set `<reg_gpio_xx_func_sel>` to 11 to enter the SWGPIO mode
- Set `<reg_gpio_xx_mode>` to 3 to enable the Cache Set/Clear output function of I/O
- Set to enable/disable the internal pull-up and pull-down functions through `<reg_gpio_xx_pu>` and `<reg_gpio_xx_pd>`

When the `<cr_gpio_tx_en>` bit in the register GPIO_CFG142 is set to 1, the data written into the FIFO by the GPIO_CFG144 register will be written to the corresponding pins one by one in order, to set the level of pin. The size of the buffer area is 128 * 16 bits.

The level state output to the pin can be set freely. With XCLK as the clock source, the value set to the `<cr_code_total_time>` bit in the register GPIO_CFG142 is one cycle:

Every 8 pins form a group. The low 8 bits and high 8 bits of the register GPIO_CFG144 set the output high/low level of 8 pins respectively. If the low 8 bits are written to 1, the corresponding pin outputs a high level. If the high 8 bits are written to 1, that outputs a low level. The bits written to 0 in this register shall be invalid. When the corresponding bits in the high 8 bits and low 8 bits are written to 1 simultaneously for the same pin, the pin outputs a high level.

The `<cr_gpio_dma_out_sel_latch>` bit in the register GPIO_CFG143 shall be set to 1. `<cr_gpio_dma_park_value>` is used to set the default level of I/O, namely 1 for high level and 0 for low level.

4.5 I/O FIFO

The depth of I/O FIFO is 128 halfwords. The `<gpio_tx_fifo_cnt>` bit in the register GPIO_CFG143 indicates the current available space of FIFO (128 by default). Every time a value is written into the GPIO_CFG144 register, the value of `<gpio_tx_fifo_cnt>` will decrease by 1. After it decreases to 0, if a value is continuously written to the register GPIO_CFG144 and `<cr_gpio_tx_fer_en>` is 1, the error interrupt will be enabled and this interrupt will occur.

When the `<cr_gpio_tx_en>` bit in the GPIO_CFG142 register is 1, the data of I/O FIFO will be sent to I/O pins one by one, and the value of `<gpio_tx_fifo_cnt>` will increment. When it is incremented to greater than `<cr_gpio_tx_fifo_th>` and `<cr_gpio_tx_fifo_en>` is 1, the FIFO interrupt is enabled and this interrupt will occur.

If the `<cr_gpio_dma_tx_en>` bit in the register CR_GPIO_CFG143 is 1, DMA is enabled to send data. If `<cr_gpio_tx_fifo_th>` is less than `<gpio_tx_fifo_cnt>`, DMA will transfer the data from the preset RAM to the buffer, whereas the interrupt flag `<r_gpio_tx_fifo_int>` will be cleared automatically.

4.6 I/O Interrupt

I/O supports various external interrupts. Setting the `<reg_gpio_xx_int_mask>` in the register GPIO_CFGxx to 0 can enable the external interrupt of the corresponding pin. `<reg_gpio_xx_int_mode_set>` is used to set the external interrupt type of that pin.

The supported interrupt types are as follows:

- Synchronous Falling Edge Interrupt
 - Based on the f32k_clk clock, the input pin level is sampled once on each rising edge of the clock. If a high level is followed by two low levels, a synchronous falling edge interrupt will be generated at this time
- Synchronous Rising Edge Interrupt
 - Based on the f32k_clk clock, the input pin level is sampled once on each rising edge of the clock. If a low level is followed by two high levels, a synchronous rising edge interrupt will be generated at this time
- Synchronous Low Level Interrupt
 - Based on the f32k_clk clock, after detecting a low level, a synchronous low-level interrupt is generated at the rising edge of the third clock
- Synchronous High Level Interrupt
 - Based on the f32k_clk clock, after detecting a high level, a synchronous high-level interrupt is generated at the rising edge of the third clock
- Synchronous Double Edge Interrupt
 - Based on the f32k_clk clock, if a high level transition to low level (low level transition to high level) is detected, a falling edge (rising edge) event will be generated. After the event is generated, at the third rising edge of the clock, synchronous double edge interrupt will be generated

- Asynchronous Falling Edge Interrupt
 - When a high-to-low transition is detected, an asynchronous falling edge interrupt is triggered immediately
- Asynchronous Rising Edge Interrupt
 - When a low-to-high transition is detected, an asynchronous rising edge interrupt is triggered immediately
- Asynchronous Low Level Interrupt
 - Based on the f32k_clk clock, the input pin level is sampled once on each rising edge of the clock. If it is low for 3 consecutive times, an asynchronous low-level interrupt is triggered
- Asynchronous High Level Interrupt
 - Based on the f32k_clk clock, the input pin level is sampled once on each rising edge of the clock. If it is high for 3 consecutive times, an asynchronous high-level interrupt will be triggered

In the interrupt function, you can obtain the interrupt-generating GPIO state through the <gpio_xx_int_stat> of the register GPIO_CFGxx, and clear the interrupt flag through <reg_gpio_xx_int_clr>.

5.1 Overview

The chip integrates one 12-bit SAR ADC, which supports 12 external analog input signals and several internal analog signals. ADC can work in single conversion mode and multi-channel scanning mode, and the conversion result is 12/14/16-bit LeftJustified mode. ADC has a FIFO with a depth of 32, which supports multiple interrupts and DMA. In addition to measuring ordinary analog signals, ADC can also measure power supply voltage, and detect temperature by measuring the internal/external diode voltage.

5.2 Features

- High performance
 - Optional 12-bit/14-bit/16-bit conversion result for output
 - Shortest ADC conversion time of 0.5 us (12-bit conversion result)
 - Optional reference voltage of 1.8V/3.3V
 - Transfer of conversion result to memory through DMA
 - Supports single channel conversion and multi-channel scanning modes
 - Single-ended and differential input modes
 - Jitter compensation
 - User-defined offset value of conversion result
 - Up to 1M for scanning mode clock and 2M for non-scanning mode clock
- Number of analog channels
 - Twelve external analog channels
 - Two internal DAC channels

- One VBAT/2 channel
- One TSEN channel

5.3 Functional Description

The block diagram of ADC module is shown as follows.

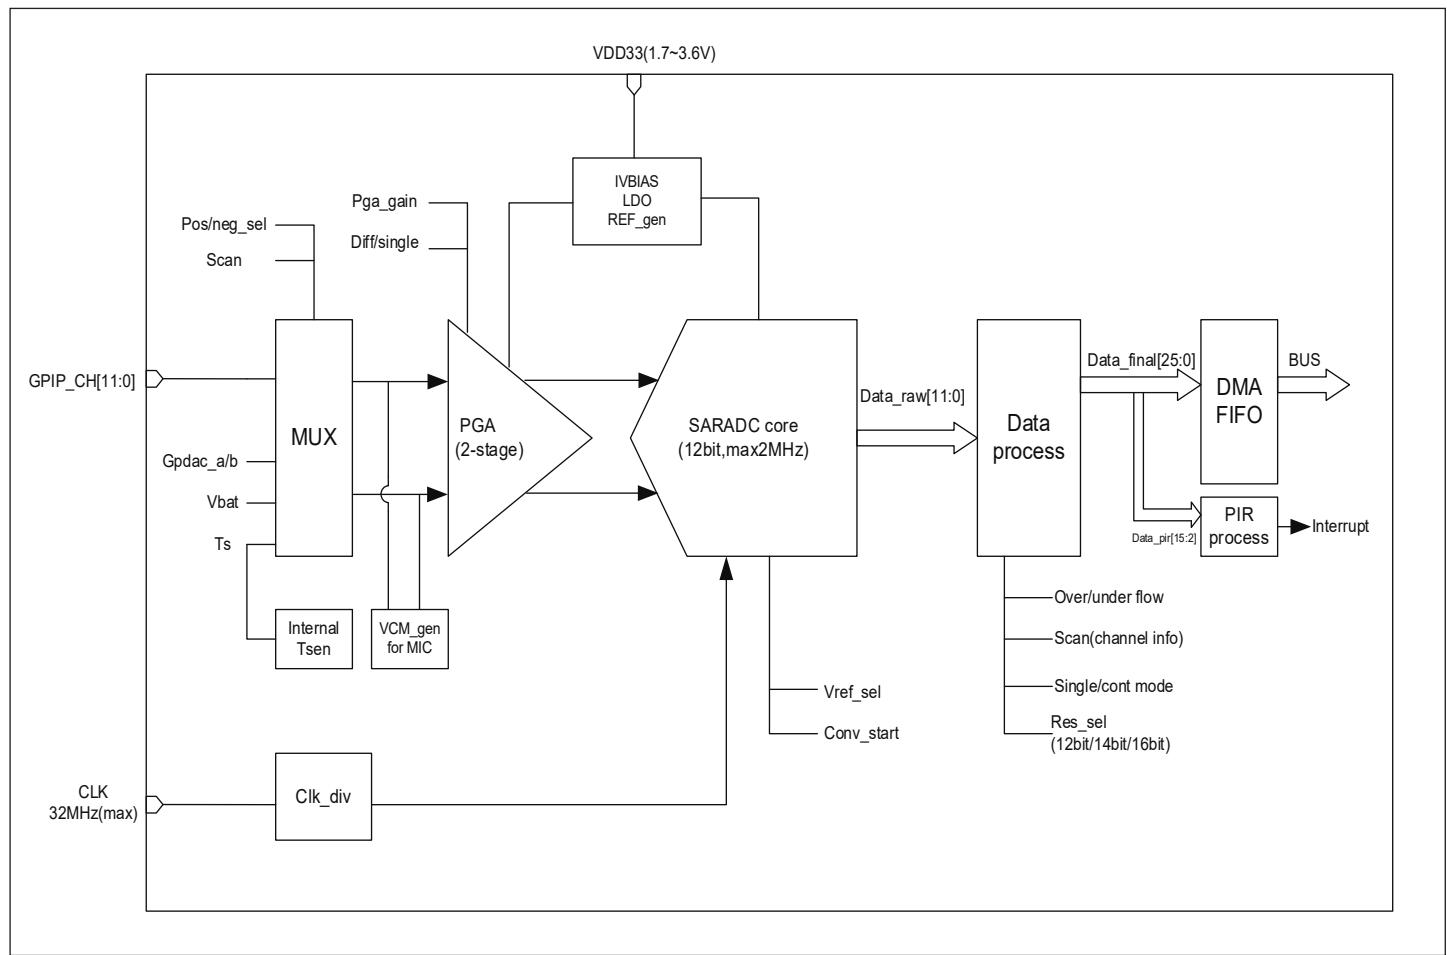

Fig. 5.1: Block Diagram of ADC

The ADC module consists of front-end input channel selector, programmable amplifier, ADC sampling module, data processing module, and FIFO.

The input channel selector is used to select the channel to be sampled, including internal and external analog signals.

The programmable amplifier is used to further process the input signal, and it is set based on the characteristics of the input signal (DC/AC) to get a more accurate conversion value.

The ADC sampling module is the most important functional module, which gets the result of conversion (12 bit) from analog signal to digital signal by successive comparison.

The data processing module further processes the conversion result, including adding channel information.

The final data will be pushed to the back-end FIFO.

5.3.1 ADC Pins and Internal Signals

Table 5.1: ADC internal signal

Internal Signal	Type	Description
VBAT/2	Input	Voltage signal divided from the power supply pin
TSEN	Input	Output voltage of internal temperature sensor
VREF	Input	Reference voltage of internal analog module
DACOUTA	Input	DAC module output
DACOUTB	Input	DAC module output

Table 5.2: ADC external pin

External Pin	Signal Type	Signal Description
VDDA	Input	Positive supply voltage of analog module
VSSA	Input	Analog module ground
ADC_CHX	Input	Analog input pins, 12 channels

5.3.2 ADC Channels

The selectable channels of ADC sampling include the input signals of external analog pins and the selectable signals inside the chip:

- ADC CH0
- ADC CH1
- ADC CH2
- ADC CH3
- ADC CH4
- ADC CH5
- ADC CH6
- ADC CH7
- ADC CH8

- ADC CH9
- ADC CH10
- ADC CH11
- DAC OUTA
- DAC OUTB
- VBAT/2
- TSEN
- VREF
- GND

It is worth noting that if VBAT/2 or TSEN is selected as the input signal to be sampled, gpadc_vbat_en or gpadc_ts_en shall be set. The ADC module supports single-ended input or differential input. For the former, GND shall be selected as the negative input channel.

5.3.3 ADC Clocks

The following figure illustrates the working clock source of the ADC module.

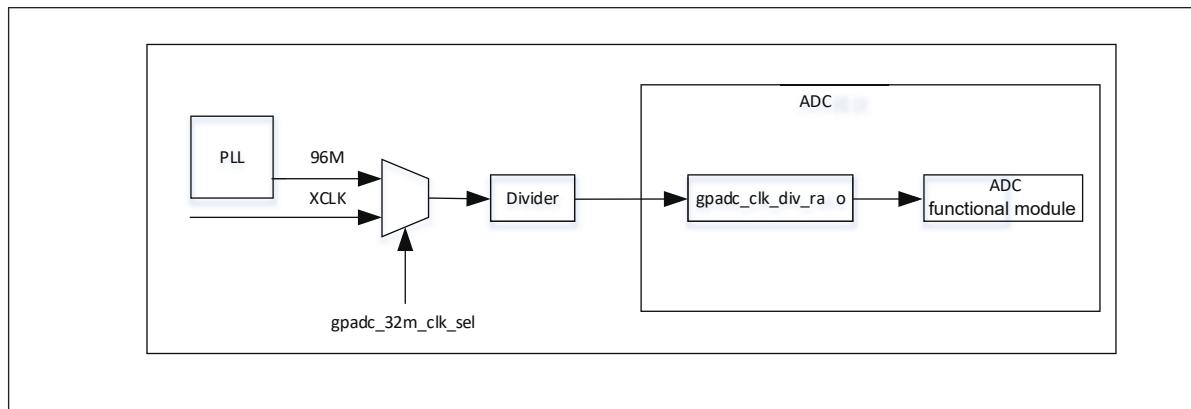

Fig. 5.2: ADC Clocks

The clock source of ADC can be the 96M from PLL, XTAL or internal RC32M. The GLB module controls the setting of clock source selection and provides clock frequency division. By default, the clock source of ADC is 96M and the clock frequency division is 2. The clock reaching the ADC module is 32M.

Inside the ADC module, clock frequency division (div=16 by default) is provided, so the default clock is 2M. Users can adjust the clock source and division factor of ADC according to the actual sampling needs.

The gpadc_32m_clk_div frequency division register is 6 bits wide (max div=64). The frequency division formula is $f_{out} = f_{source} / (gpadc_32m_clk_div + 1)$. The gpadc_clk_div_ratio frequency division register of 3 bits width is located inside the ADC module. Its frequency division values are defined as follows:

- 3' b000: div=1
- 3' b001: div=4
- 3' b010: div=8
- 3' b011: div=12
- 3' b100: div=16
- 3' b101: div=20
- 3' b110: div=24
- 3' b111: div=32

5.3.4 ADC Conversion Mode

ADC supports single channel conversion and scanning conversion modes.

- Single Channel Conversion Mode
 - Select the positive input channel by setting <gpadc_pos_sel> and the negative input channel by setting <gpadc_neg_sel> of the register gpadc_reg_cmd
 - Set the <gpadc_cont_conv_en> control bit in the register gpadc_reg_config1 to 0, indicating single channel conversion, then set the gpadc_conv_start control bit to start conversion

In the scanning conversion mode, the gpadc_cont_conv_en control bit is set to 1. ADC performs conversion one by one according to the number of conversion channels set by the gpadc_scan_length control bit and the channel sequence set by gpadc_reg_scn_posX (X = 1, 2) and gpadc_reg_scn_negX (X = 1, 2) register sets. The conversion result is automatically pushed into the ADC FIFO. The channels set by the gpadc_reg_scn_posX (X = 1, 2) and gpadc_reg_scn_negX (X = 1, 2) register sets can be the same, which means that the user can sample a channel multiple times for conversion.

The conversion result of ADC is usually pushed into FIFO. Users need to set the FIFO data receiving threshold interrupt according to the actual number of conversion channels, and this threshold interrupt is used as the ADC Conversion Complete Interrupt.

5.3.5 ADC Result

The register gpadc_raw_data stores the original result of ADC. In the single-ended mode, the valid bit of data is 12 bits, without sign bit. In the differential mode, the most significant bit (MSB) is the sign bit, and the remaining 11 bits represent the conversion result.

The register gpadc_data_out stores the ADC result, which contains the ADC result, sign bit, and channel information. The data format is as follows:

Table 5.3: Meaning of ADC Conversion Result

BitS	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0			
meaning	Positive channel number					Negative channel number					Conversion result																		

In the above table, bit21-bit25 indicates the positive channel number, and bit16-bit20 indicates the negative channel number, while bit0-bit15 indicates the converted value.

The gpadc_res_sel control bit can set the bits of the conversion result to 12 bits, 14 bits, and 16 bits, of which 14 bits and 16 bits are the result of multiple sampling. The optional setting values are as follows:

- 3' b000 12bit 2MS/s, OSR=1
- 3' b001 14bit 125kS/s, OSR=16
- 3' b010 14bit 31.25kS/s, OSR=64
- 3' b011 16bit 15.625KS/s, OSR=128
- 3' b100 16bit 7.8125KS/s, OSR=256

In the left-justified ADC conversion result, when 12 bits are selected, bit15-bit4 of the conversion result is valid; when 14 bits are selected, bit15-bit2 is valid; and when 16 bits are selected, bit15-bit0 is valid. Similarly, in the differential mode, the MSB is the sign bit. Namely, when 14 bits are selected, bit15 is the sign bit and bit14 is the MSB, while bit14-bit2 is the conversion result. In the single-ended mode, there is no sign bit. Namely, when 12 bits are selected, bit15-bit4 is the conversion result and bit15 is the MSB.

In practice, ADC results are generally pushed into FIFO, which is especially important in the multi-channel scanning mode. Therefore, users usually obtain conversion results from ADC FIFO. The data format of ADC FIFO is the same as that in the register gpadc_data_out.

5.3.6 ADC Interrupt

The ADC module will generate interrupts upon positive or negative sampling over-range, and such interrupts can be masked by gpadc_pos_satur_mask and gpadc_neg_satur_mask. When interrupts are generated, the interrupt status can be queried through the registers gpadc_pos_satur and gpadc_neg_satur. Interrupts can be cleared through gpadc_pos_satur_clr and gpadc_neg_satur_clr. This function can be used to check whether the input voltage is abnormal.

5.3.7 ADC FIFO

The ADC module has a FIFO with a depth of 32 and its data width is 26 bits. When the ADC completes conversion, the result will be automatically pushed into the FIFO. ADC FIFO has the following statuses and interrupt management functions:

- FIFO: full
- FIFO: non-empty
- FIFO Overrun interrupt
- FIFO Underrun interrupt

When an interrupt is generated, the interrupt flag can be cleared by the corresponding clear bit.

ADC FIFO enables users to obtain data through query, interrupt, and DMA modes.

Query mode

CPU polls the gpadc_rdy bit: When the control bit is set, it indicates that there are valid data in FIFO. CPU can get the amount of FIFO data through gpadc_fifo_data_count and read out these data from FIFO.

Interrupt mode

If gpadc_rdy_mask is set to 0 in CPU, ADC will generate an interrupt when data is pushed into FIFO. In the interrupt function, the user can get the amount of FIFO data through gpadc_fifo_data_count and read out these data from FIFO, and then set gpadc_rdy_clr to clear the interrupt.

DMA mode

If the user sets the gpadc_dma_en control bit, DMA can transfer the conversion data to the memory. In the DMA mode, after the data volume threshold is set for ADC FIFO to send DMA requests through gpadc_fifo_thl, when receiving a request, DMA will automatically transfer the specified number of results from FIFO to the corresponding memory according to the user defined parameters.

5.3.8 ADC Setup Process

Set ADC clock

According to the required ADC conversion speed, determine the working clock of ADC, set the ADC clock source and frequency division of the GLB module, and determine the final working clock frequency of the ADC module based on the gpadc_clk_div_ratio.

Set GPIO according to the channel used

According to the analog pin used, determine the channel number used, and initialize the corresponding GPIO to analog function. But note that when setting GPIO as analog input, set it as floating input instead of pull-up or pull-down.

Set the channel to convert

According to the used analog channel and conversion mode, set the corresponding channel register. For single channel conversion, set the conversion channel information in the registers gpadc_pos_sel and gpadc_neg_sel. In the multi-channel scanning mode, set gpadc_scan_length, gpadc_reg_scn_posX, and gpadc_reg_scn_negX according to the number of channels to be scanned and the scanning sequence.

Set the data read method

Based on the data reading mode introduced by ADC FIFO, select the mode used and set the register. If DMA is used, configure one channel of DMA, and assist ADC FIFO in transferring data.

Start conversion

Finally, set gpadc_res_sel to select the precision of data conversion result, and then set gpadc_global_en=1 and gpadc_conv_start=1 to start ADC conversion. When conversion is completed, to convert again, it is necessary to set gpadc_conv_start to 0 first and then to 1 to trigger the conversion again.

5.3.9 VBAT Measurement

The VBAT/2 here measures the voltage of the chip VDD33, not the external lithium battery voltage. If you need to measure the voltage of power supply sources like lithium battery, you can divide the voltage and input it into the GPIO analog channel of ADC. Measuring the voltage of VDD33 can reduce the use of GPIO.

The VBAT/2 voltage measured by the ADC module is divided, and the actual voltage input to the ADC module is half of that of VDD33, namely $VBAT/2=VDD33/2$. As the voltage is divided, to ensure a high accuracy, it is suggested to select 1.8 V reference voltage for ADC, and enable the single-ended mode. The positive input voltage is set to VBAT/2 and the negative input voltage is set to GND. Gpadc_vbat_en is set to 1. After conversion starts, the corresponding conversion result can be multiplied by 2 to get the voltage of VDD33.

5.3.10 TSEN Measurement

ADC can measure the voltage of internal or external diode. As the voltage difference of diode is related to temperature, the ambient temperature can be calculated from the measured voltage of diode. So it is called temperature sensor (TSEN).

The measurement principle of TSEN is the curve fitted by the voltage difference (ΔV) with the change of temperature, where ΔV is produced by measuring two different currents on a diode. No matter an external or internal diode is measured, the final output value is related to temperature and can be expressed as $\Delta(ADC_{out})=7.753T+X$. As long as we know the voltage, we know the temperature T. X indicates an offset value, which can be used as a standard value. Before actual use, X shall be determined first. The chip manufacturer will measure $\Delta(ADC_{out})$ at a standard temperature, such as 25°C room temperature, before the chip leaves the factory, to obtain X. In actual use, the user can get the temperature T according to the formula $T=[\Delta(ADC_{out})X]/7.753$.

When TSEN is used, it is recommended to set ADC to the 16bits mode, reduce error through multiple sampling, select 1.8 V reference voltage to improve accuracy, and set gpadc_ts_en to 1 to enable the TSEN function. If internal diode is selected, gpadc_tsext_sel=0. If external diode is selected, gpadc_tsext_sel=1. The positive input channel is selected according to actual needs, namely TSEN channel for the internal diode or the analog GPIO channel for the

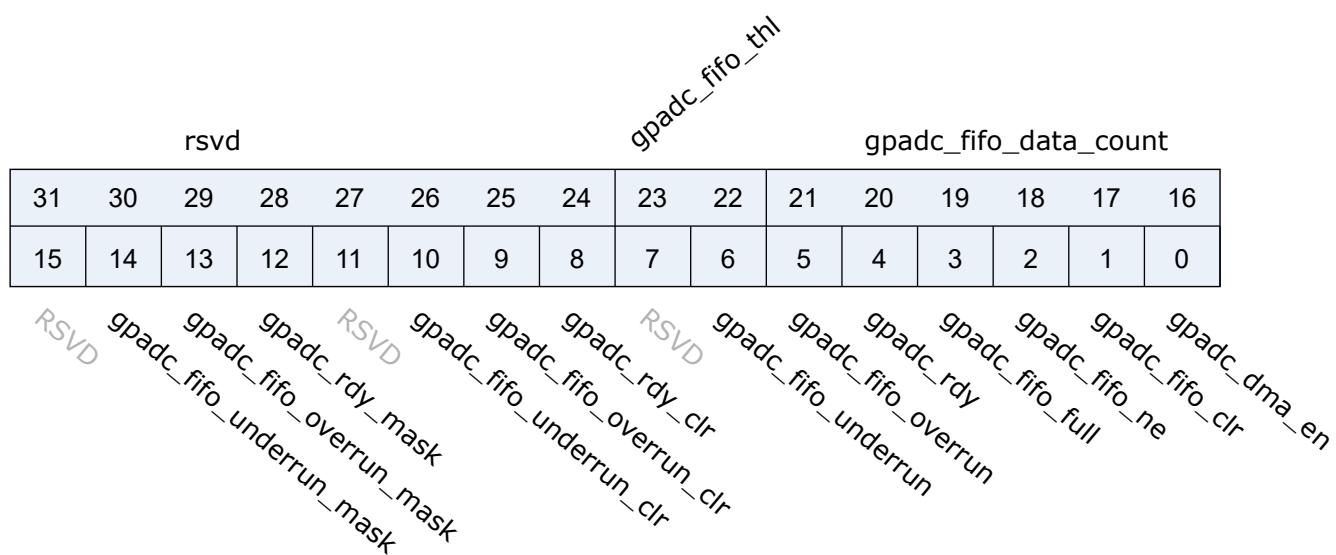

external diode. The negative input channel is set to GND. After finishing the above settings, set gpadc_tsvbe_low=0 to start measurement, and get the measurement result V0. Then set gpadc_tsvbe_low=1 to start measurement, and get the measurement result V1, $\Delta(\text{ADC_out}) = V1V0$. The temperature T is calculated based on the formula $T = [\Delta(\text{ADC_out})]X]/7.753$.

6.1 Overview

The chip integrates a 10bits digital-to-analog converter (DAC) with FIFO depth of 1, and supports two DAC modulation outputs. DAC can be used for playing audio and modulating transmitter voltage.

6.2 Features

- Modulation accuracy of 10bits
- Optional input clocks of 32k, 16k, 8k or 512k
- Allows DMA to transfer memory to DAC modulation registers
- Supports dual-channel playback and DMA transfer mode
- Output pins of DAC are fixed as GPIO4 for ChannelA and GPIO11 for ChannelB

6.3 Functional Description

The block diagram of DAC is shown as follows.

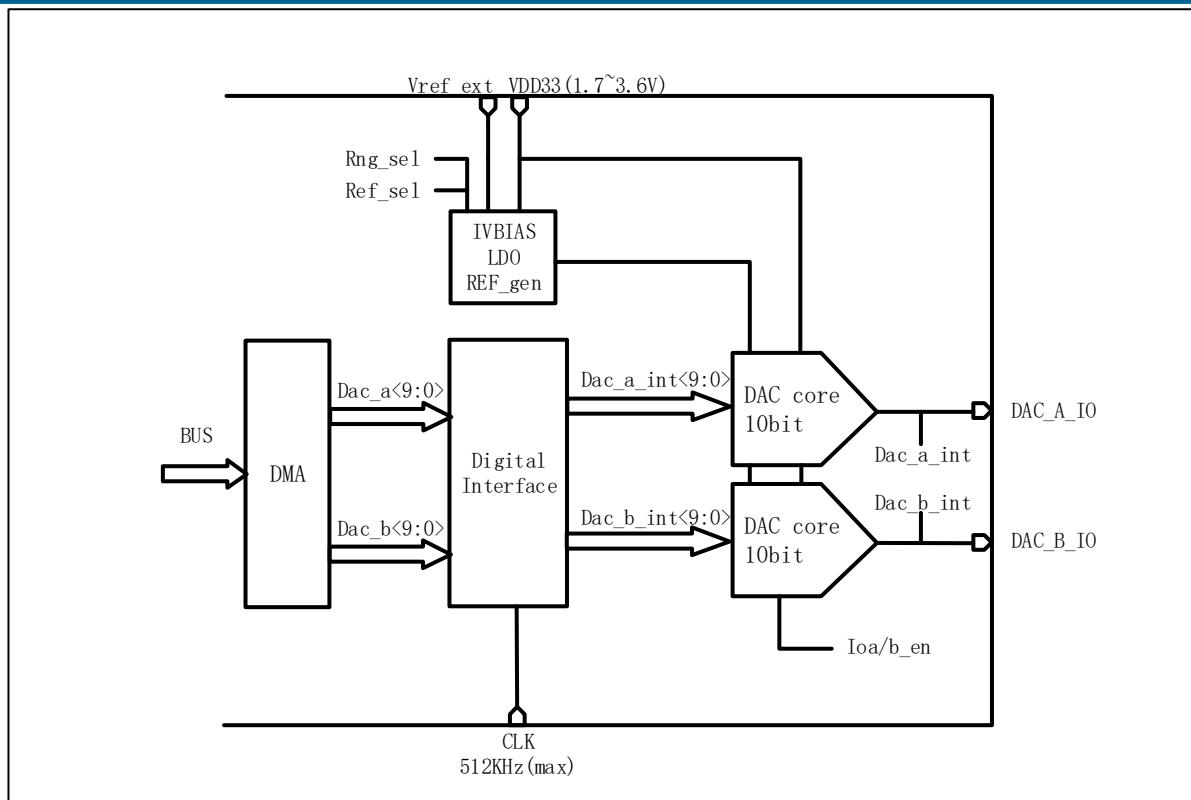

Fig. 6.1: Block Diagram of DAC

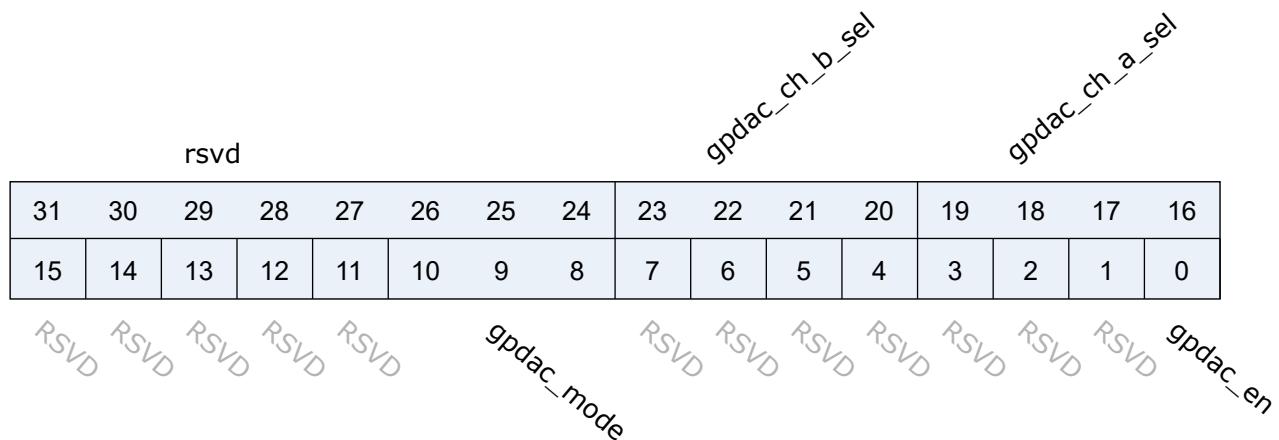

- Supports up to two modulated outputs
- Supports dual-channel playback and DMA data transfer
- Supports the DMA data interface with a length of 32bit, in which the high 16 bits will be modulated on the pin of ChannelA and the low 16 bits will be modulated on the pin of ChannelB

7.1 Overview

Direct Memory Access (DMA), a kind of memory access technique, can directly read and write system memory independently without relying on processor. Under the same processor load, DMA is a fast way to transfer data.

It is provided with 3 independent DMA controllers, of which DMA0 and DMA2 have 8 independent dedicated channels, and DMA1 has 4 such channels, managing data transmission between peripherals and memory to enhance bus efficiency. DMA supports the transfer from memory to memory, memory to peripherals, and peripheral to memory, and provides the LLI linked list function. The software configures the data transfer size, data source address, and destination address.

7.2 Features

- Three DMA controllers: DMA0, DMA1, and DMA2
- DMA0 and DMA2 have 8 independent dedicated channels, and DMA1 has 4 such channels
- Independent control source and destination access width (single byte, double bytes, and four bytes)
- Each channel acts as a read-write cache independently
- Each channel can be triggered by independent peripheral hardware or software
- Peripherals supported by DMA0 and DMA1: UART, I2C, SPI, ADC, IR, GPIO, Audio, I2S, and PDM
- Peripherals supported by DMA2: UART, I2C, SPI, DBI, and DSI
- Eight kinds of process control
 - DMA process control, source memory, destination memory
 - DMA process control, source memory, destination peripherals
 - DMA process control, source peripherals, destination memory

- DMA process control, source peripherals, destination peripherals
 - Destination peripheral process control, source peripherals, destination peripherals
 - Destination peripheral process control, source memory, destination peripherals
 - Source peripheral process control, source peripherals, destination memory
 - Source peripheral process control, source peripherals, destination peripherals
- Supports the LLI linked list function to improve DMA efficiency

7.3 Functional Description

7.3.1 Operating Principle

When a device tries to directly transfer data to another device through the bus, it will first send a DMA request signal to CPU. The peripheral submits a request through DMA to take over control of the bus from CPU. After receiving this signal, CPU will respond to the DMA signal according to the priority of signal and the order of the DMA request after the current bus cycle is over. When CPU responds to a DMA request for a device interface, it will give up control of the bus.

Under the control of DMA controllers, peripherals and memory exchange data directly without CPU intervention. After data is transferred, the device will send a DMA end signal to CPU and return the control of the bus.

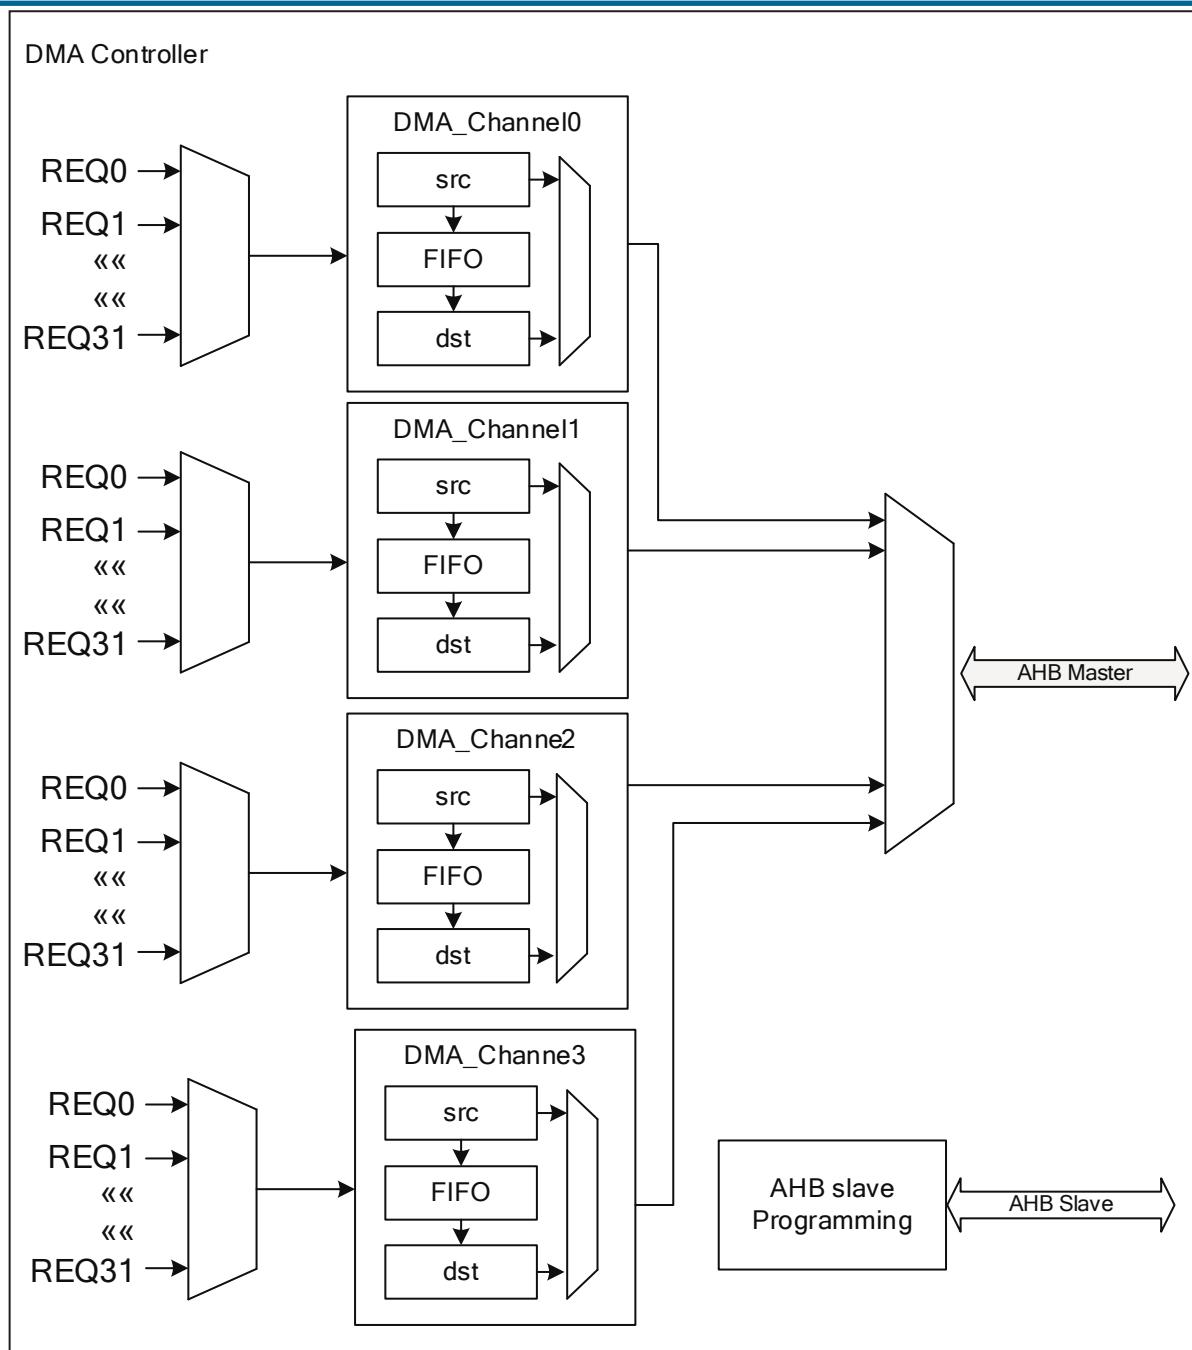

Fig. 7.1: Block Diagram of DMA

DMA has one AHB Master interfaces and one AHB Slave interface. Based on the current configuration requirements, the AHB Master interface actively accesses the memory or peripherals through system bus, and serves as a data transfer port. The AHB Slave interface for configuring DMA only supports 32bit access.

7.3.2 DMA Channel Configuration

DMA0 and DMA2 support 8 channels, and DMA1 supports 4 channels. All channels can run simultaneously without interference. Here is the configuration process of DMA channel x:

1. Set the 32-bit source address in the register DMA_C0SrcAddr.
2. Set the 32-bit destination address in the register DMA_C0DstAddr.
3. Automatic address accumulation: You can set to enable/disable the automatic address accumulation mode by configuring the SI (source) and DI (destination) in the register DMA_C0Control. When it is set to 1, this mode is enabled.
4. You can set the width of transferred data by configuring the SWidth (source) and DWidth (destination) bits in the register DMA_C0Control, including single byte, double bytes, four bytes, and eight bytes (for DMA2 only) options.
5. You can set the Burst type by configuring the SBSIZE (source) and DBSIZE (destination) bits in the register DMA_C0Control, including INCR1, INCR4, INCR8, and INCR16 options.
6. It is worth noting that in the configured combination, the single burst of DMA0 and DMA1 must not exceed 16 bytes, and that of DMA2 must not exceed 128 bytes.
7. Range of data transfer length: 0-4095

7.3.3 Supported Peripherals

You can determine the peripherals supported by the current DMA by configuring the SrcPeripheral (source) and DstPeripheral (destination). The relationship between peripheral types and configuration values is shown as follows:

Value	DMA0	DMA1	DMA2
0	UART0_RX	UART0_RX	UART3_RX
1	UART0_TX	UART0_TX	UART3_TX
2	UART1_RX	UART1_RX	SPI1_RX
3	UART1_TX	UART1_TX	SPI1_TX
4	UART2_RX	UART2_RX	-
5	UART2_TX	UART2_TX	-
6	I2C0_RX	I2C0_RX	I2C2_RX
7	I2C0_TX	I2C0_TX	I2C2_TX
8	IR_TX	IR_TX	I2C3_RX
9	GPIO_TX	GPIO_TX	I2C3_TX
10	SPI0_RX	SPI0_RX	DSI_RX
11	SPI0_TX	SPI0_TX	DSI_TX
12	AUDIO_RX	AUDIO_RX	-
13	AUDIO_TX	AUDIO_TX	-
14	I2C1_RX	I2C1_RX	-
15	I2C1_TX	I2C1_TX	-
16	I2S_RX	I2S_RX	-
17	I2S_TX	I2S_TX	-
18	PDM_RX	PDM_RX	-
22	GPADC_RX	GPADC_RX	DBI_TX
23	GPADC_TX	GPADC_TX	-

Fig. 7.2: Peripheral Type Selection

Partial peripheral configuration examples:

UART uses DMA to transfer data

When UART sends data packets, DMA can greatly shorten the CPU's processing time, so that CPU resources will not be highly wasted, especially when UART sends and receives a large number of data packets (such as sending and receiving instructions frequently).

For example, the UART0 transfer is configured as follows:

1. Set the value of the SrcPeripheral bit in the register DMA_C0Config to 1. That is, set Source peripheral to UART0_TX
2. Set the value of the DstPeripheral in the register DMA_C0Config to 0. That is, set Destination peripheral to UART0_RX

I2C uses DMA to transfer data

Configuration process:

1. Set the value of the SrcPeripheral bit in the register DMA_C0Config to 7. That is, set Source peripheral to I2C0_TX
2. Set the value of the DstPeripheral in the register DMA_C0Config to 6. That is, set Destination peripheral to I2C0_RX

SPI uses DMA to transfer data

Configuration process:

1. Set the value of the SrcPeripheral bit in the register DMA_C0Config to 11. That is, set Source peripheral to SPI0_TX
2. Set the value of the DstPeripheral in the register DMA_C0Config to 10. That is, set Destination peripheral to SPI0_RX

ADC0/1 use DMA to transfer data

Configuration process:

1. Set the value of the SrcPeripheral bit in the register DMA_C0Config to 22/23. That is, set Source peripheral to GPADC0/GPADC1.

7.3.4 Linked List Mode

DMA supports the linked list working mode. During a DMA read or write operation, data can be filled in the next linked list. After the data transfer of the current linked list is completed, the start address of the next linked list can be obtained by reading the value of the register DMA_C0LLI, to directly transfer the data of the next linked list. This ensures continuous and uninterrupted work during DMA transfer, and improves the efficiency of CPU and DMA.

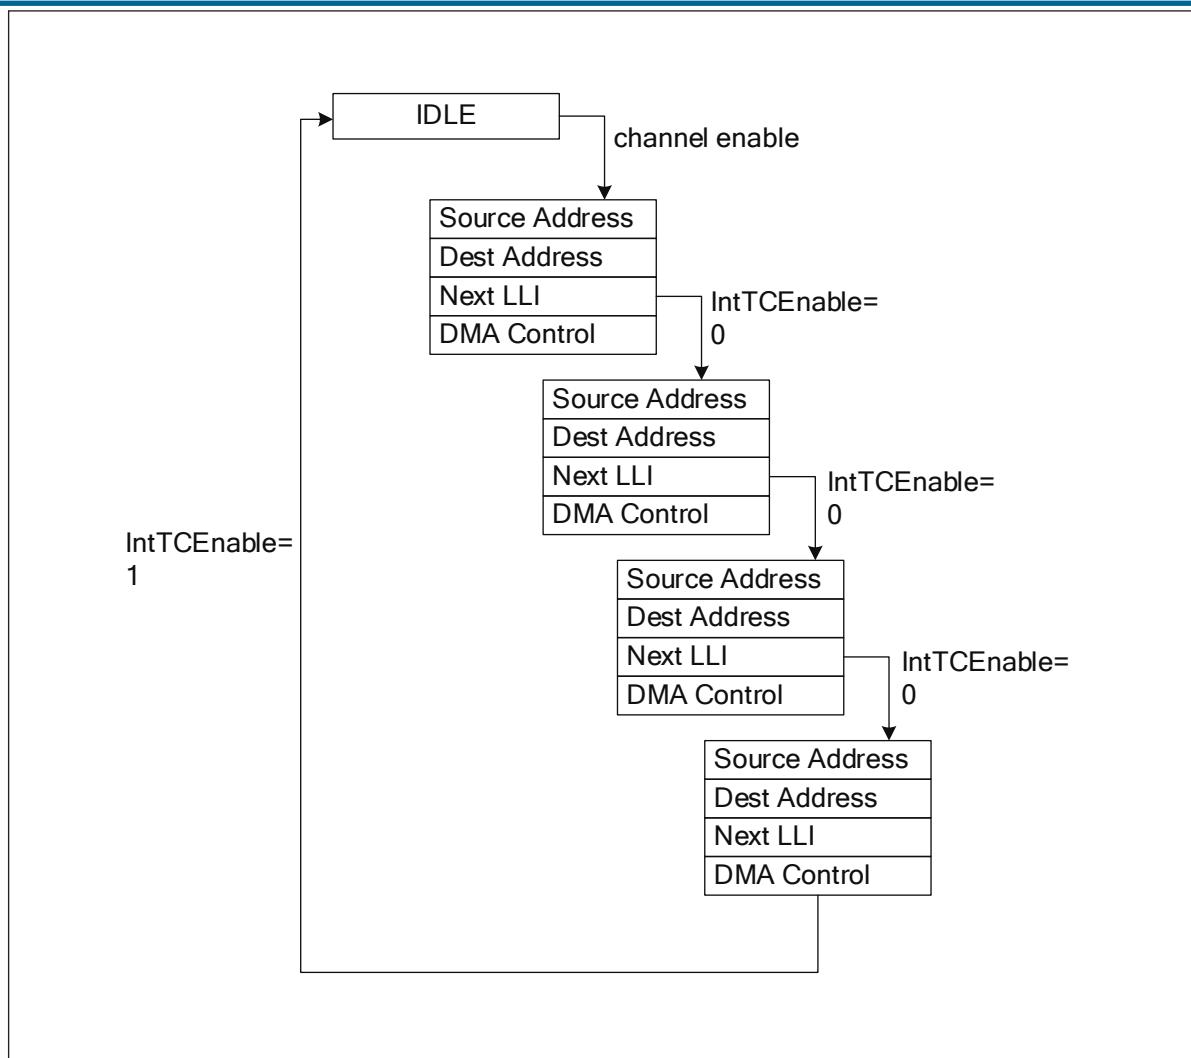

Fig. 7.3: LLI Framework

7.3.5 DMA Interrupt

- DMA_INT_TCOMPLETED
 - Data transfer complete interrupt: This interrupt will be generated when a data transfer is completed
- DMA_INT_ERR
 - Data transfer error interrupt: This interrupt will be generated when an error occurs during data transfer

7.4 Transfer Mode

7.4.1 Memory to Memory

After this mode is enabled, DMA will transfer the data from the source address to the destination address based on the preset TransferSize. Upon transfer completed, the DMA controller will automatically return to the idle state and wait for the next transfer.

Configuration process:

1. Set the DMA_C0SrcAddr value of the register to the source memory address
2. Set the DMA_C0DstAddr value of the register to the destination memory address
3. Select a transfer mode, and set the value of the FlowCntrl bit in the register DMA_C0Config to 0, namely selecting the memorytomemory mode
4. Set the values of the corresponding bits in the register DMA_C0Control: Set the DI and SI bits to 1 to enable the automatic address accumulation mode; set the transfer width of the source and destination through SWidth and DWidth respectively; and set the burst type of the source and the destination through SBSIZE and DBSIZe respectively
5. Select a proper channel, enable DMA, and complete data transfer

7.4.2 Memory to Peripherals

In this mode, DMA will transfer the data from the source to the internal cache according to the preset TransferSize. The transfer will automatically pause when the cache space is insufficient and continue when there is enough cache space until the preset TransferSize is met.

Moreover, when the destination peripheral request is triggered, the target configuration will be burst to the destination address, and it will automatically return to the idle state until the preset TransferSize is met and wait for the next transfer.

Configuration process:

1. Set the DMA_C0SrcAddr value of the register to the source memory address
2. Set the DMA_C0DstAddr value of the register to the destination peripheral address
3. Select a transfer mode, and set the value of the FlowCntrl bit in the register DMA_C0Config to 1, namely selecting the Memorytoperipheral mode
4. Set the values of the corresponding bits in the register DMA_C0Control: Set the DI and SI bits to 1 to enable the automatic address accumulation mode; set the transfer width of the source and destination through SWidth and DWidth respectively; and set the burst type of the source and the destination through SBSIZE and DBSIZe respectively
5. Select a proper channel, enable DMA, and complete data transfer

7.4.3 Peripheral to Memory

In this mode, when the source peripheral request is triggered, the source configuration will be burst into the cache until the preset TransferSize is met. Moreover, when the internal cache is enough for one burst to the destination, DMA will automatically transfer the cached content to the destination address, automatically return to the idle state until the preset TransferSize is met, and wait for the next transfer.

Configuration process:

1. Set the DMA_C0SrcAddr value of the register to the source peripheral address
2. Set the DMA_C0DstAddr value of the register to the destination memory address
3. Select a transfer mode, and set the value of the FlowCntrl bit in the register DMA_C0Config to 2, namely selecting the Peripheraltomemory mode
4. Set the values of the corresponding bits in the register DMA_C0Control: Set the DI and SI bits to 1 to enable the automatic address accumulation mode; set the transfer width of the source and destination through SWidth and DWidth respectively; and set the burst type of the source and the destination through SBSIZE and DBSIZe respectively
5. Select a proper channel, enable DMA, and complete data transfer

8.1 Overview

The 2 Dimensional Direct Memory Access (DMA2D or 2D DMA) is a technique extended from 1D DMA that allows a 2D DMA controller to transfer data in the set strides (see the DMA section for details about 1D DMA). The memory address of data can be non-contiguous, incremented or decremented at a certain interval, or unchanged. The 2D DMA controller has 2 independent dedicated lanes, managing data transmission between peripherals and memory to enhance bus efficiency. It supports the transfer from memory to memory, memory to peripherals, and peripheral to memory, and provides the LLI linked list function.

8.2 Features

- Two dedicated independent lanes
- Configurable as 1D DMA or 2D DMA
- Independent control source and destination access width (single byte, double bytes, and four bytes)
- Each lane acts as a read-write cache independently
- Each lane can be triggered by independent peripheral hardware or software
- Supported peripherals: UART, I2C, SPI, DBI, and DSI
- Eight kinds of process control
 - DMA process control, source memory, destination memory
 - DMA process control, source memory, destination peripherals
 - DMA process control, source peripherals, destination memory
 - DMA process control, source peripherals, destination peripherals
 - Destination peripheral process control, source peripherals, destination peripherals

- Destination peripheral process control, source memory, destination peripherals
 - Source peripheral process control, source peripherals, destination memory
 - Source peripheral process control, source peripherals, destination peripherals
- Supports the LLI linked list function to improve DMA efficiency, and configures whether to trigger interrupt for each node separately
 - Exclusive features of 2D DMA:
 - Supports translation of 8/16/32-bit images in any direction
 - Supports rotation of 8/16/32-bit images at 90°/180°/270°
 - Supports horizontal/vertical folding of 8/16/32-bit images
 - Supports filling by 8/16/32-bit images
 - Supports 8/16/24/32-bit Color Key

8.3 Functional Description

8.3.1 Operating Principle

On the basis of 1D DMA, 2D DMA adds the SRC XINCR, SRC XCOUNT, SRC YINCR, and SRC YCOUNT; and adds the DEST XINCR, DEST XCOUNT, and DEST YINCR. DEST YCOUNT will not be configured, as it will be derived from other values. Here the stride value can be negative. The 2D DMA transfer can be viewed as a nested loop, where the outer loop is specified by YCOUNT and each time the loop address increments by YINCR bytes (decrements when YINCR is negative); the inner loop is specified by XCOUNT and each time the loop address increments XINCR bytes (decrements when XINCR is negative). The working principle is illustrated as follows:

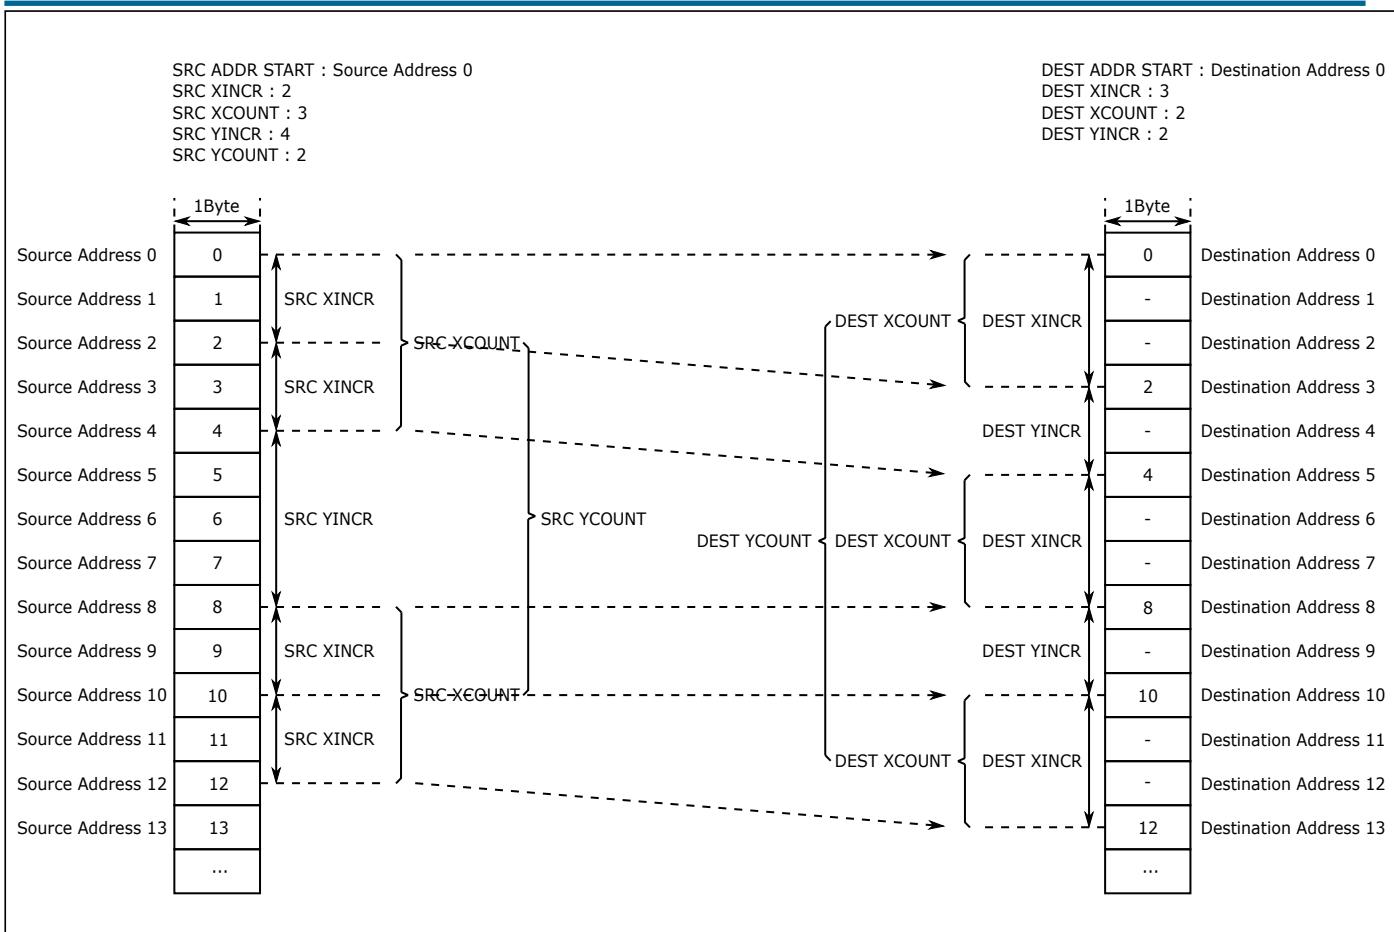

Fig. 8.1: Operating Principle

8.3.2 Image Translation

If the memory data is considered as a rectangular image, the image can be translated by setting the stride and loop values, as shown below:

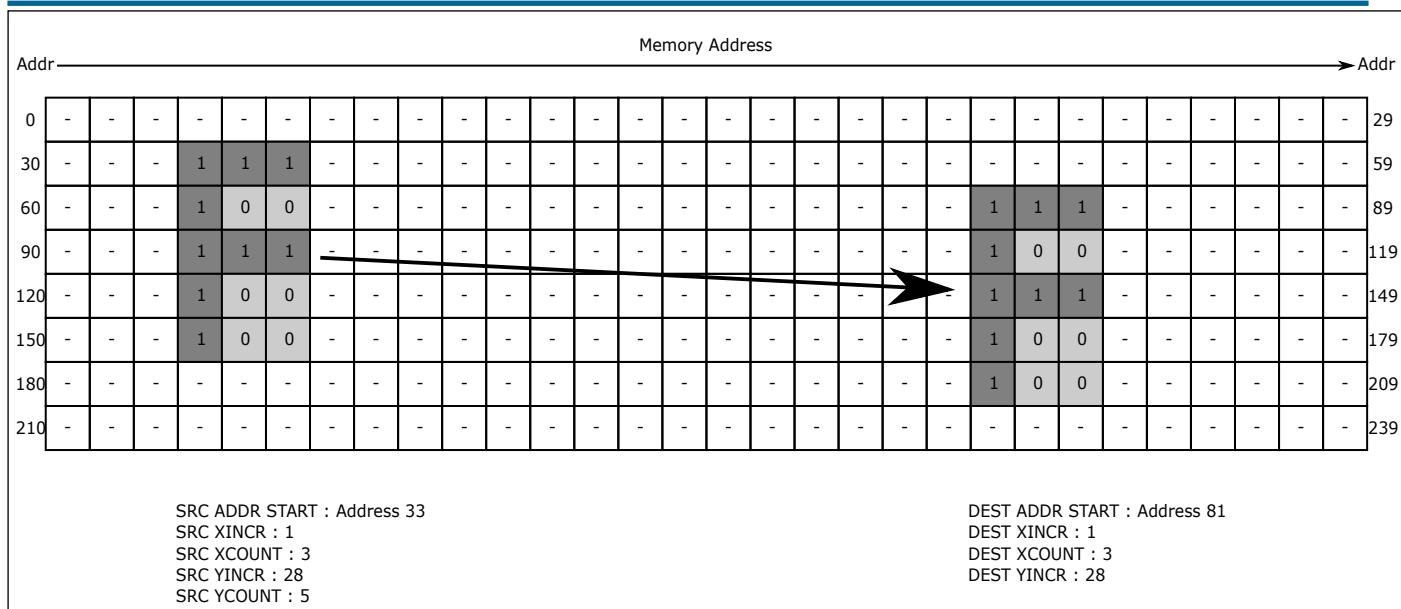

Fig. 8.2: Image Translation

As shown in the figure, it is assumed that a pixel width (P) is 8 bit, and the transfer width of 2D DMA is set to 8 bit. In an $M \times N$ image (30×8 in the figure), a rectangular area of $W \times H$ (3×5 in the figure) is translated from the coordinate (x_1, y_1) [(3, 1) in the figure] to the coordinate (x_2, y_2) [(21, 2) in the figure]. The start address of image data starts from addr0 (0 in the figure). Relevant parameters of 2D DMA are calculated as follows:

- SRC ADDR START = $\text{addr0} + (M \cdot y_1 + x_1) \cdot P = 0 + (30 \cdot 1 + 3) \cdot 1 = 33$
- SRC XINCR = $P = 1$
- SRC XCOUNT = $W = 3$
- SRC YINCR = $(M - (W - 1)) \cdot P = (30 - (3 - 1)) \cdot 1 = 28$
- SRC YCOUNT = $H = 5$
- DEST ADDR START = $\text{addr0} + (M \cdot y_2 + x_2) \cdot P = 0 + (30 \cdot 2 + 21) \cdot 1 = 81$
- DEST XINCR = $P = 1$
- DEST XCOUNT = $W = 3$
- DEST YINCR = $(M - (W - 1)) \cdot P = (30 - (3 - 1)) \cdot 1 = 28$

8.3.3 Image Rotation

If the memory data is considered as a rectangular image, the image can be rotated at 90°/180°/270° by setting the stride and loop values, as shown below:

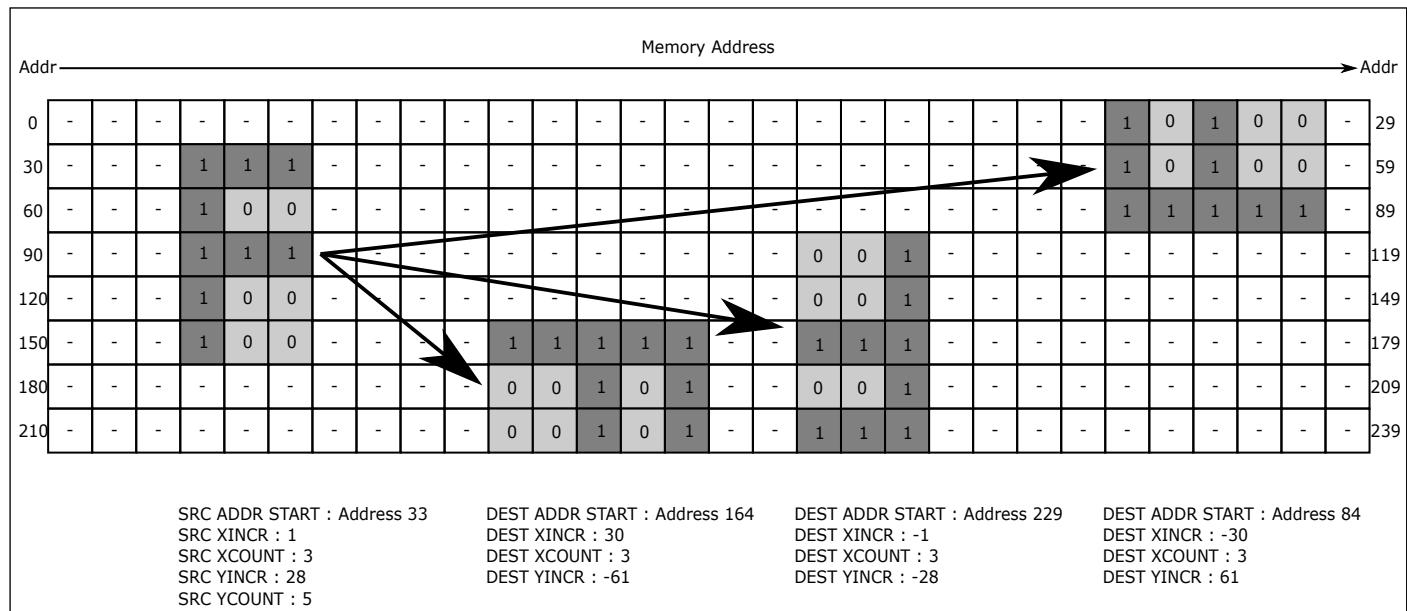

Fig. 8.3: Image Rotation

As shown in the figure, it is assumed that a pixel width (P) is 8 bit, and the transfer width of 2D DMA is set to 8 bit. In an M × N image (30 × 8 in the figure), a rectangular area of W × H (3 × 5 in the figure) is rotated clockwise at 90° from the coordinate (x1, y1) [(3, 1) in the figure] to the coordinate (x2, y2) [(14, 5) in the figure]. The start address of image data starts from addr0 (0 in the figure). Relevant parameters of 2D DMA are calculated as follows:

- SRC ADDR START = addr0+(M*y1+x1)*P = 0+(30*1+3)*1 = 33
- SRC XINCR = P = 1
- SRC XCOUNT = W = 3
- SRC YINCR = (M-(W-1))*P = (30-(3-1))*1 = 28
- SRC YCOUNT = H = 5
- DEST ADDR START = addr0+(M*y2+x2)*P = 0+(30*5+14)*1 = 164
- DEST XINCR = M*P = 30*1 = 30
- DEST XCOUNT = W = 3
- DEST YINCR = -(M*(W-1)+1)*P = -(30*(3-1)+1)*1 = -61

For the clockwise rotation of the rectangular area at 180° from the coordinate (x1, y1) [(3, 1) in the figure] to the coordinate (x3, y3) [(19, 7) in the figure], relevant parameters are calculated as follows:

- SRC ADDR START = $\text{addr}_0 + (\text{M} * \text{y}_1 + \text{x}_1) * \text{P} = 0 + (30 * 1 + 3) * 1 = 33$
- SRC XINCR = P = 1
- SRC XCOUNT = W = 3
- SRC YINCR = $(\text{M} - (\text{W} - 1)) * \text{P} = (30 - (3 - 1)) * 1 = 28$
- SRC YCOUNT = H = 5
- DEST ADDR START = $\text{addr}_0 + (\text{M} * \text{y}_3 + \text{x}_3) * \text{P} = 0 + (30 * 7 + 19) * 1 = 229$
- DEST XINCR = -P = -1
- DEST XCOUNT = W = 3
- DEST YINCR = $-(\text{M} - (\text{W} - 1)) * \text{P} = -(30 - (3 - 1)) * 1 = -28$

For the clockwise rotation of the rectangular area at 270° from the coordinate (x_1, y_1) [(3, 1) in the figure] to the coordinate (x_4, y_4) [(24, 2) in the figure], relevant parameters are calculated as follows:

- SRC ADDR START = $\text{addr}_0 + (\text{M} * \text{y}_1 + \text{x}_1) * \text{P} = 0 + (30 * 1 + 3) * 1 = 33$
- SRC XINCR = P = 1
- SRC XCOUNT = W = 3
- SRC YINCR = $(\text{M} * (\text{W} - 1)) * \text{P} = (30 * (3 - 1)) * 1 = 28$
- SRC YCOUNT = H = 5
- DEST ADDR START = $\text{addr}_0 + (\text{M} * \text{y}_4 + \text{x}_4) * \text{P} = 0 + (30 * 2 + 24) * 1 = 84$
- DEST XINCR = $-\text{M} * \text{P} = -30 * 1 = -30$
- DEST XCOUNT = W = 3
- DEST YINCR = $(\text{M} * (\text{W} - 1) + 1) * \text{P} = (30 * (3 - 1) + 1) * 1 = 61$

8.3.4 Image Folding

If the memory data is considered as a rectangular image, the image can be folded horizontally or vertically by setting the stride and loop values, as shown below:

		Memory Address			
Addr					Addr
0	-	-	-	-	29
30	-	-	1	1	59
60	-	-	1	0	89
90	-	-	1	1	119
120	-	-	1	0	149
150	-	-	1	0	179
180	-	-	-	-	209
210	-	-	-	-	239
SRC ADDR START : Address 33		DEST ADDR START : Address 105		DEST ADDR START : Address 142	
SRC XINCR : 1		DEST XINCR : -1		DEST XINCR : 1	
SRC XCOUNT : 3		DEST XCOUNT : 3		DEST XCOUNT : 3	
SRC YINCR : 28		DEST YINCR : 32		DEST YINCR : -32	
SRC YCOUNT : 5					

Fig. 8.4: Image Folding

As shown in the figure, it is assumed that a pixel width (P) is 8 bit, and the transfer width of 2D DMA is set to 8 bit. In an $M \times N$ image (30×8 in the figure), a rectangular area of $W \times H$ (3×5 in the figure) is folded horizontally from the coordinate (x_1, y_1) [(3, 1) in the figure] to the coordinate (x_2, y_2) [(15, 3) in the figure]. The start address of image data starts from addr0 (0 in the figure). Relevant parameters of 2D DMA are calculated as follows:

- SRC ADDR START = $\text{addr0} + (M \cdot y_1 + x_1) \cdot P = 0 + (30 \cdot 1 + 3) \cdot 1 = 33$
- SRC XINCR = $P = 1$
- SRC XCOUNT = $W = 3$
- SRC YINCR = $(M - (W - 1)) \cdot P = (30 - (3 - 1)) \cdot 1 = 28$
- SRC YCOUNT = $H = 5$
- DEST ADDR START = $\text{addr0} + (M \cdot y_2 + x_2) \cdot P = 0 + (30 \cdot 3 + 15) \cdot 1 = 105$
- DEST XINCR = $-P = -1$
- DEST XCOUNT = $W = 3$
- DEST YINCR = $(M + (W - 1)) \cdot P = (30 + (3 - 1)) \cdot 1 = 32$

For vertical folding of the rectangular area from the coordinate (x_1, y_1) [(3, 1) in the figure] to the coordinate (x_3, y_3) [(22, 4) in the figure], relevant parameters are calculated as follows:

- SRC ADDR START = $\text{addr0} + (M \cdot y_1 + x_1) \cdot P = 0 + (30 \cdot 1 + 3) \cdot 1 = 33$
- SRC XINCR = $P = 1$
- SRC XCOUNT = $W = 3$

- SRC YINCR = $(M-(W-1)) \times P = (30-(3-1)) \times 1 = 28$
- SRC YCOUNT = H = 5
- DEST ADDR START = $addr0 + (M \times y3 + x3) \times P = 0 + (30 \times 4 + 22) \times 1 = 142$
- DEST XINCR = P = 1
- DEST XCOUNT = W = 3
- DEST YINCR = $-(M+(W-1)) \times P = -(30+(3-1)) \times 1 = -32$

8.3.5 Image Filling

If the memory data is considered as a rectangular image, the image can be filled by setting the stride and loop values, as shown below:

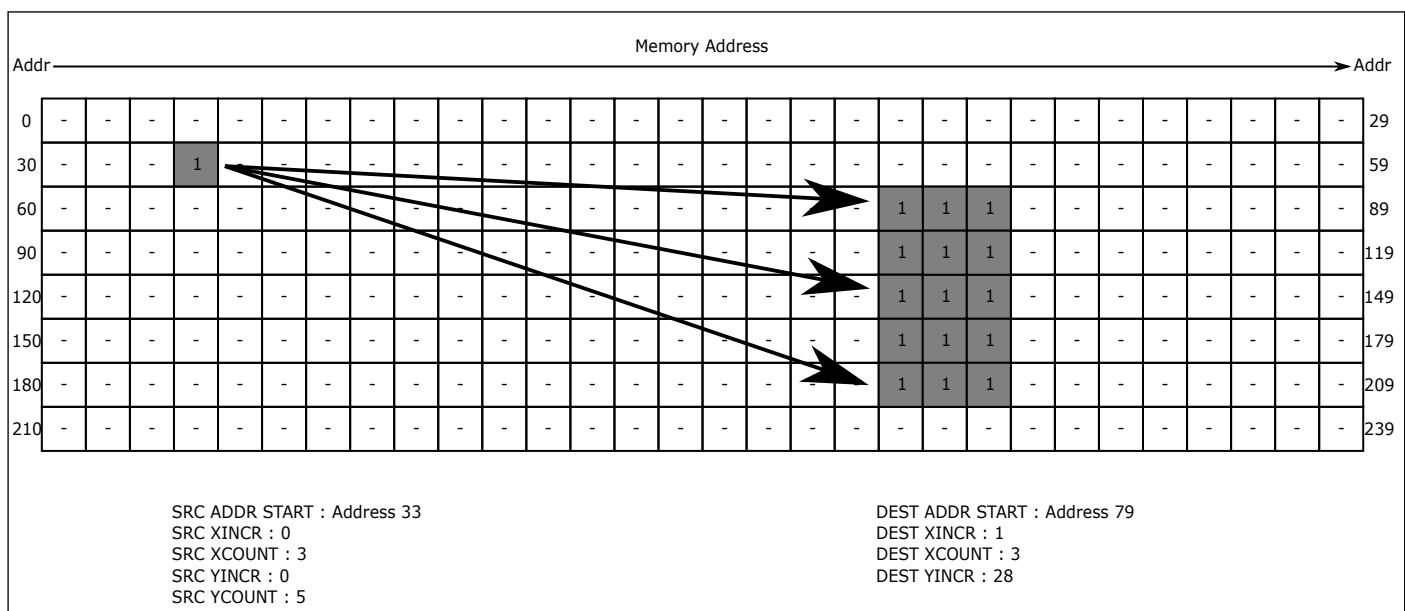

Fig. 8.5: Image Filling

As shown in the figure, it is assumed that a pixel width (P) is 8 bit, and the transfer width of 2D DMA is set to 8 bit. In an $M \times N$ image (30×8 in the figure), a rectangular area of $W \times H$ (3×5 in the figure) with starting coordinate $(x2, y2)$ [$(19, 2)$ in the figure] is filled by the value of the coordinate $(x1, y1)$ [$(3, 1)$ in the figure]. The start address of image data starts from $addr0$ (0 in the figure). Relevant parameters of 2D DMA are calculated as follows:

- SRC ADDR START = $addr0 + (M \times y1 + x1) \times P = 0 + (30 \times 1 + 3) \times 1 = 33$
- SRC XINCR = 0
- SRC XCOUNT = W = 3
- SRC YINCR = 0
- SRC YCOUNT = H = 5

- DEST ADDR START = $addr0 + (M * y2 + x2) * P = 0 + (30 * 2 + 19) * 1 = 79$
 - DEST XINCR = $P = 1$
 - DEST XCOUNT = $W = 3$
 - DEST YINCR = $(M - (W - 1)) * P = (30 - (3 - 1)) * 1 = 28$

8.3.6 Color Key

When Color Key is enabled, if 2D DMA encounters a value equal to the preset Color Key value during data transfer, it skips the value and the original value is still stored in the skipped address. The width of Color Key can be set to 8/16/24/32-bit. The working principle is shown below:

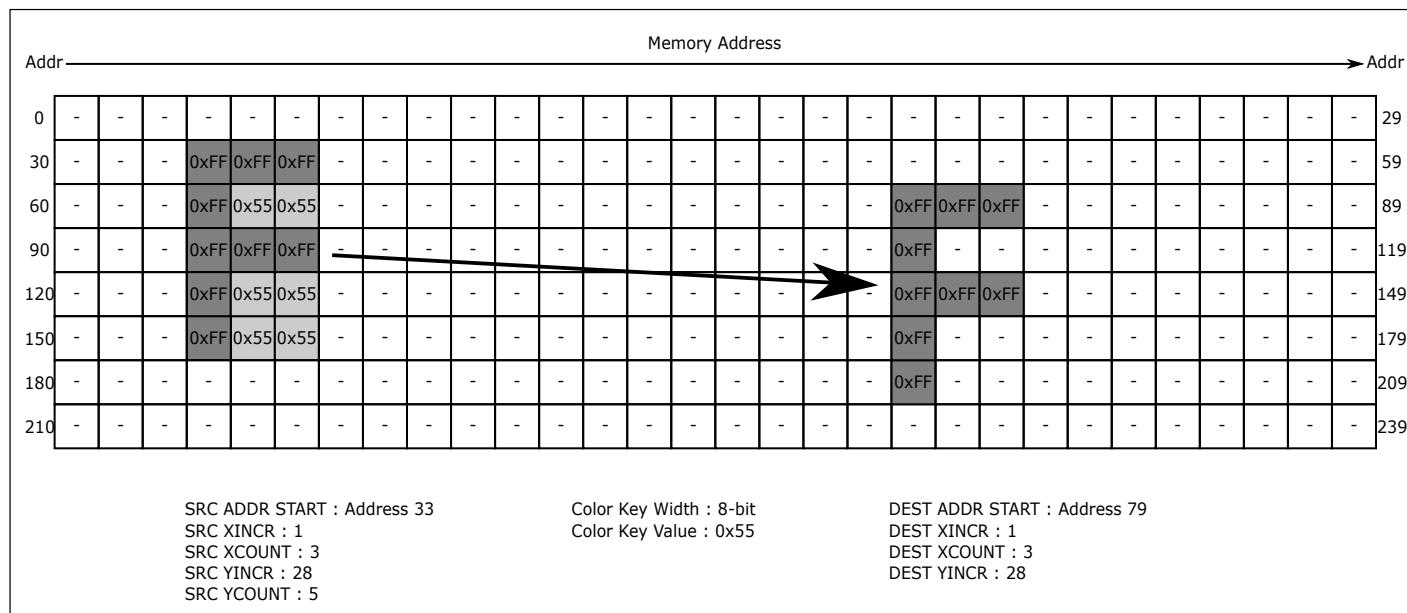

Fig. 8.6: Color Key

As shown in the above figure, the width of Color Key is set to 8 bit and the Key value is set to 0x55. When transferring the F-shaped rectangular area, 2D DMA skips the 0x55 value. So it can be seen from the right side that only the F-shaped rectangular area is transferred and the area that contains the 0x55 value is not transferred.

9.1 Overview

LZ4 is a lossless data compression algorithm that features extremely fast decompression speed and average compression ratio. LZ4D is a functional module for decompression of data blocks compressed using LZ4. LZ4D contains a status and control register set used to set the start address of the input compressed data, the output address of the decompressed data, and the decompression status and optional interrupt configuration.

9.2 Features

- Supports data blocks compressed using LZ4
- Supports decompression of data blocks compressed at different levels
- Supports decompression of multiple compressed data blocks
- Event flags for decompression completion and errors
- Generates a corresponding interrupt when an event occurs

9.3 Functional Description

The module gets the compressed data blocks from the source address through bus access, decompresses them using the internal algorithm, and writes the decompressed data to the specified destination address. During decompression, the module updates relevant registers and sets flags for events including successful decompression and decompression errors. In turn, under these event statuses, the module can request interrupts from the CPU.

9.4 Clock

LZ4D Module requires one work clock.

9.5 Programming Flow

9.5.1 Data Decompression

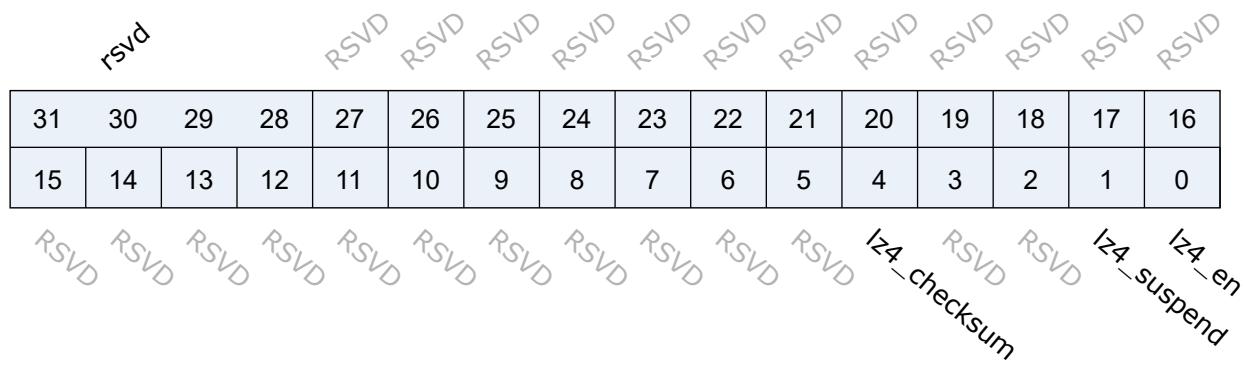

- Turn on the module’s clock
- Disable the module, write the address of the raw data to be decompressed (excluding compressed file header) to the start address register for source data
- Prepare a sufficient contiguous memory to hold the decompressed data, with a recommended length aligned on 4-byte boundary. Write the address of this memory block to the start address register for destination data
- If interrupts are required, install an interrupt handler function and set the corresponding interrupt enable bit
- In the control register, the module will start decompression once enabled
- If a “complete interrupt” is enabled, then wait for the “complete interrupt”
- If no interrupt is enabled, read the status register and then wait for the completion of decompression

10.1 Overview

The Display Bus Interface (DBI), also known as MCU interface, is an interface protocol defined by MIPI Alliance for communicating with display screens. The data and control lines of the DBI protocol are multiplexed, and the driven display module must have GRAM.

DBI is subdivided into MIPI DBI Type A, MIPI DBI Type B, and MIPI DBI Type C modes. The hardware interfaces and data sampling in different modes are different. For example, MIPI DBI Type A uses falling edge sampling (based on Motorola 6800 bus), while MIPI DBI Type B uses the rising edge sampling (based on Intel 8080 bus).

10.2 Features

- Meets MIPI® Alliance standard
- Supports Type B and Type C modes
 - Type B is an 8-bit data interface
 - Type C supports 3Line and 4Line
- Supports 8 input pixel formats:
 - RGBA8888
 - BGRA8888
 - ARGB8888
 - ABGR8888
 - RGB888
 - BGR888
 - RGB565

– BGR565

- Supported output pixel formats: RGB565, RGB666 and RGB888
- Multiple interrupt control
- Supports DMA transfer mode

10.3 Functional Description

The block diagram of DBI module is shown as follows.

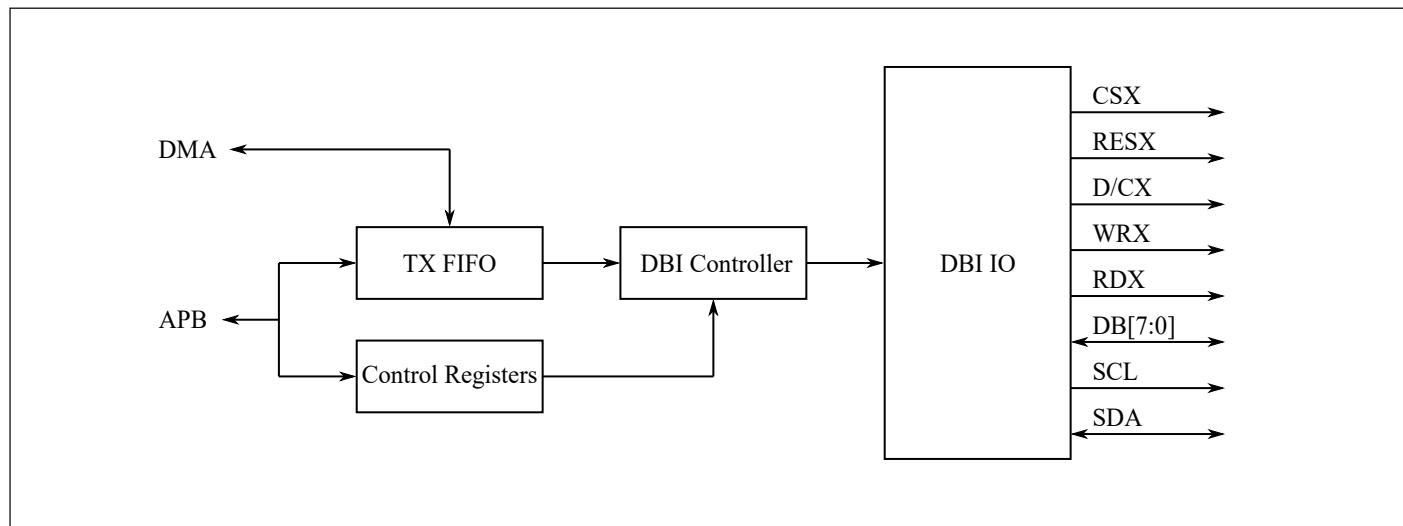

Fig. 10.1: Block Diagram of DBI

10.3.1 DBI Type B

10.3.1.1 Write Timing

The DBI Type B mode has 8-bit parallel data lines, and the timing of MCU writing data to the display module is shown as follows:

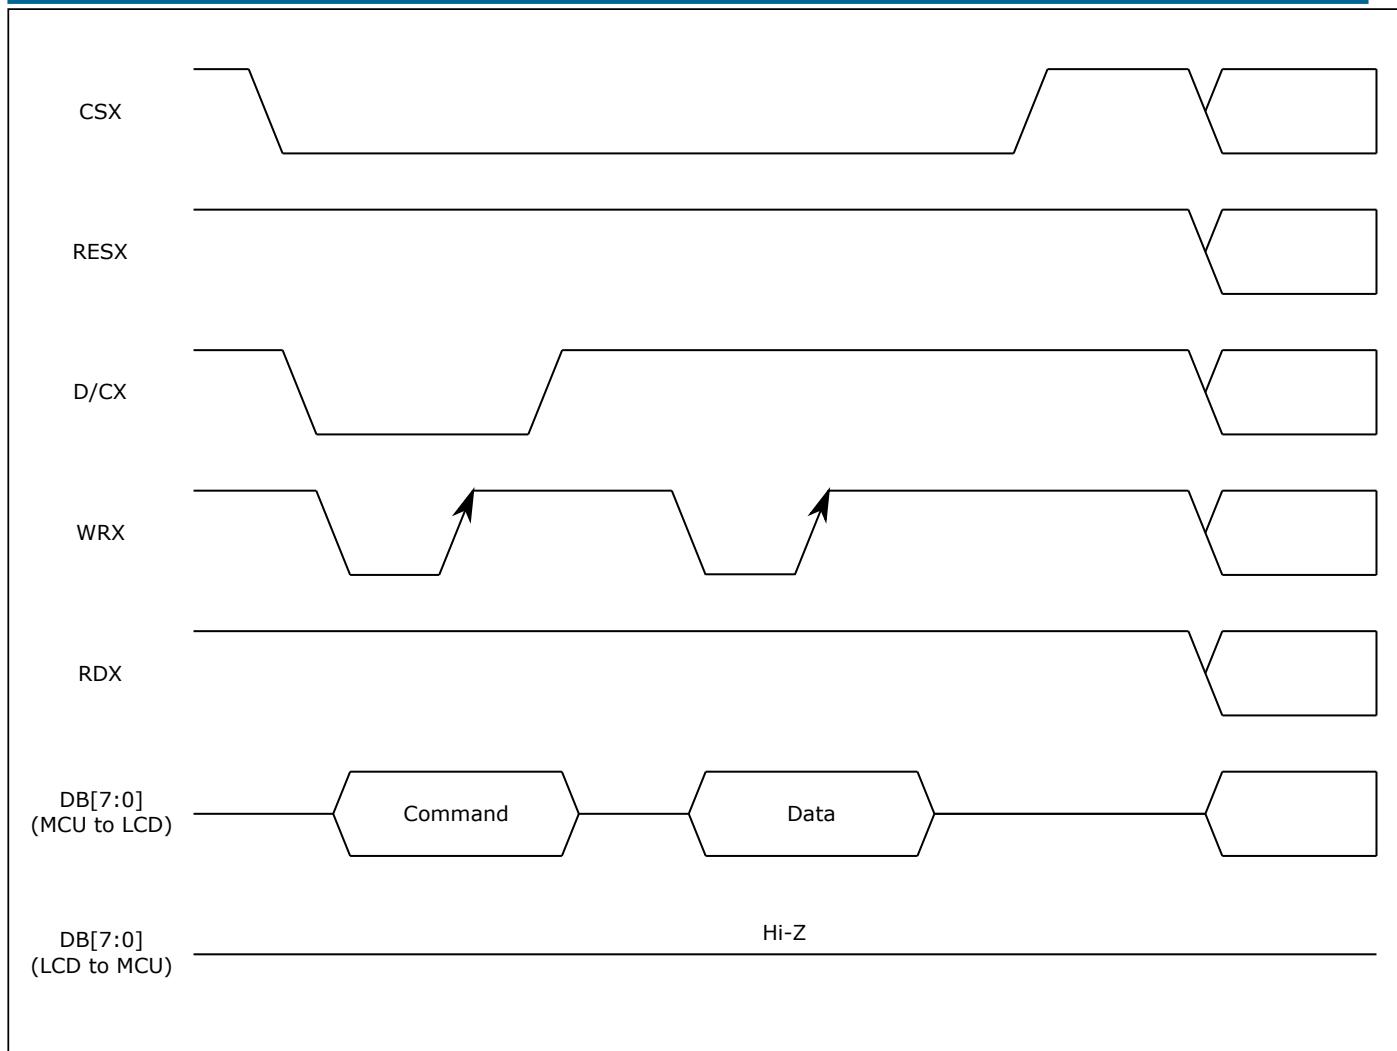

Fig. 10.2: Write Timing

- CSX: chip select signal. When the signal is Low, the display module will be selected; when it is High, the display module will ignore all other interface signals.
- RESX: external reset signal. When the signal is Low, the display module will be reset.
- D/CX: data/command signal. When the signal is 0, the DB[7:0] bit is a command; when the signal is 1, the DB[7:0] bit is the RAM data or command parameter.
- WRX: parallel data write strobe signal. The signal is driven from high to low in the write cycle and then pulled back to high. The display module reads the information transmitted by MCU at the rising edge of the signal. This is an asynchronous signal and can be terminated if not in use.
- RDX: parallel data read strobe signal. The signal is driven from high to low and then pulled back to high in the read cycle. MCU reads the information transmitted by the display module at the rising edge of the signal. This is an asynchronous signal and can be terminated if not in use.
- DB[7:0]: 8-bit data signal, used to transmit commands, command parameters or data

10.3.1.2 Read Timing

The timing of MCU reading data from the display module is shown as follows:

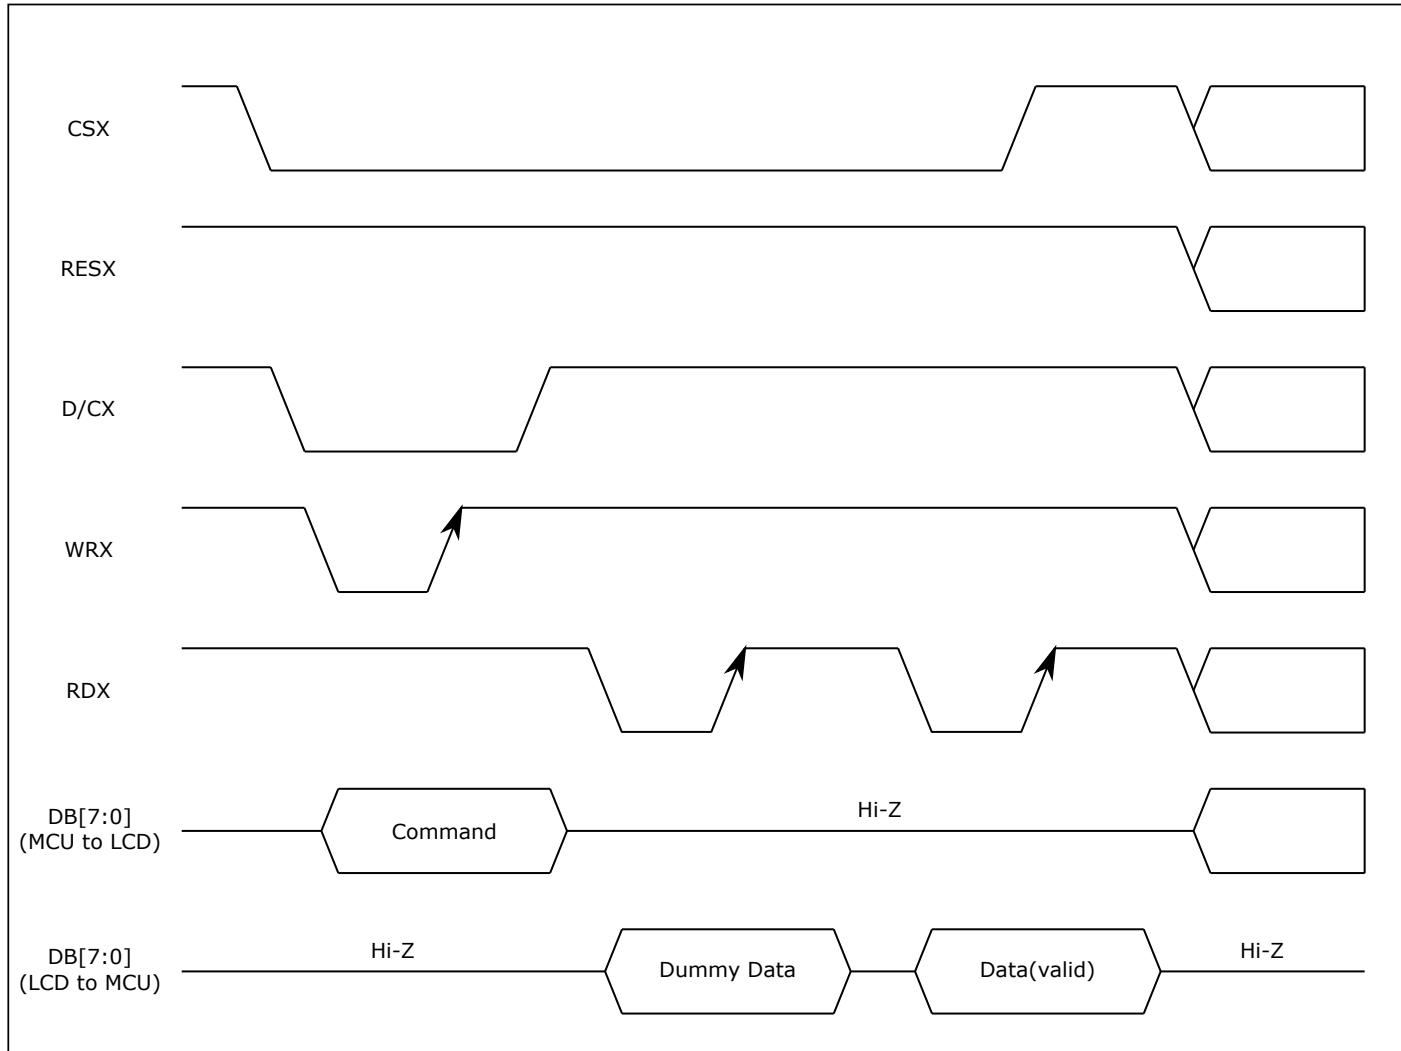

Fig. 10.3: Read Timing

10.3.1.3 Output RGB565

The data output in RGB565 format is shown as follows:

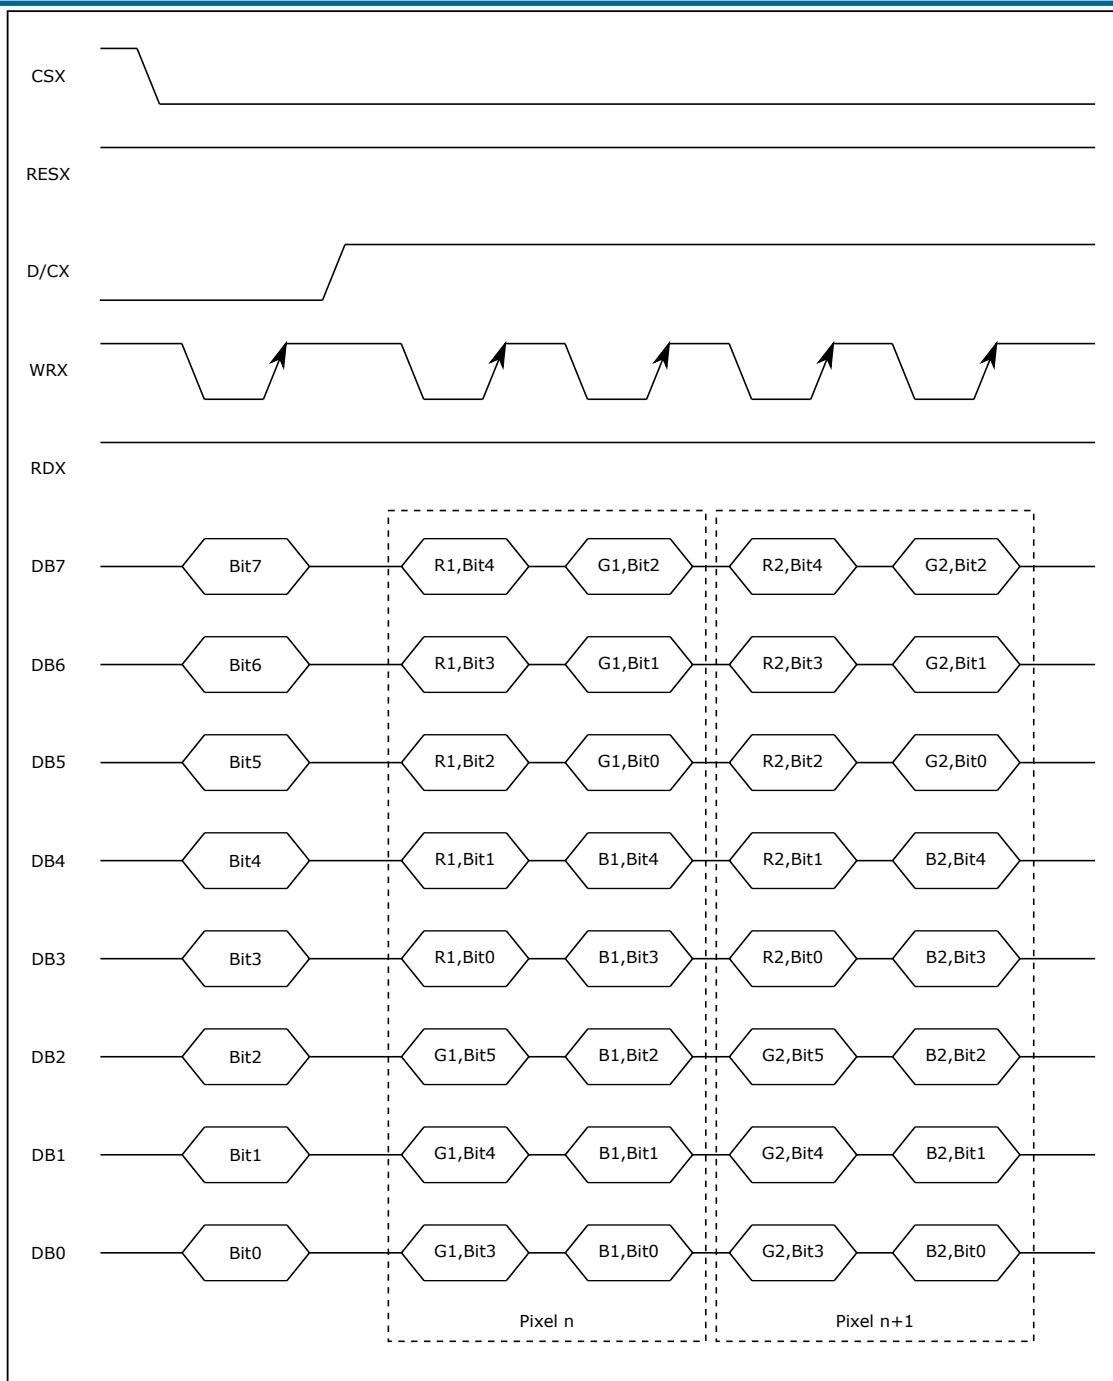

Fig. 10.4: RGB565 Output

10.3.1.4 Output RGB666

The data output in RGB666 format is shown as follows:

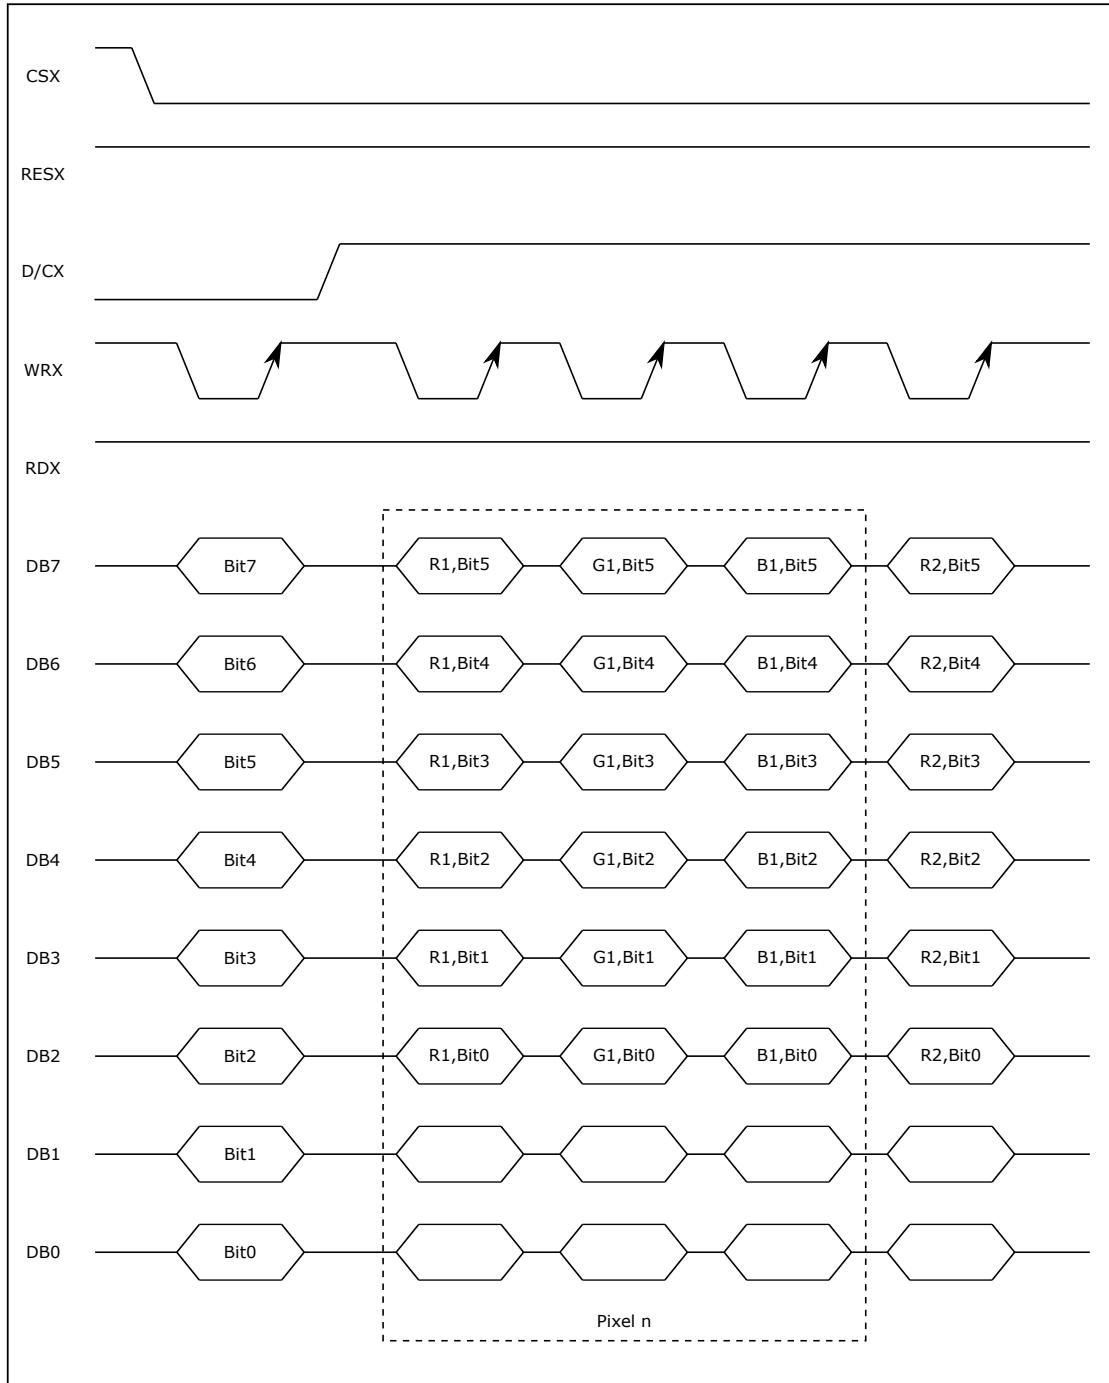

Fig. 10.5: RGB666 Output

10.3.1.5 Output RGB888

The data output in RGB888 format is shown as follows:

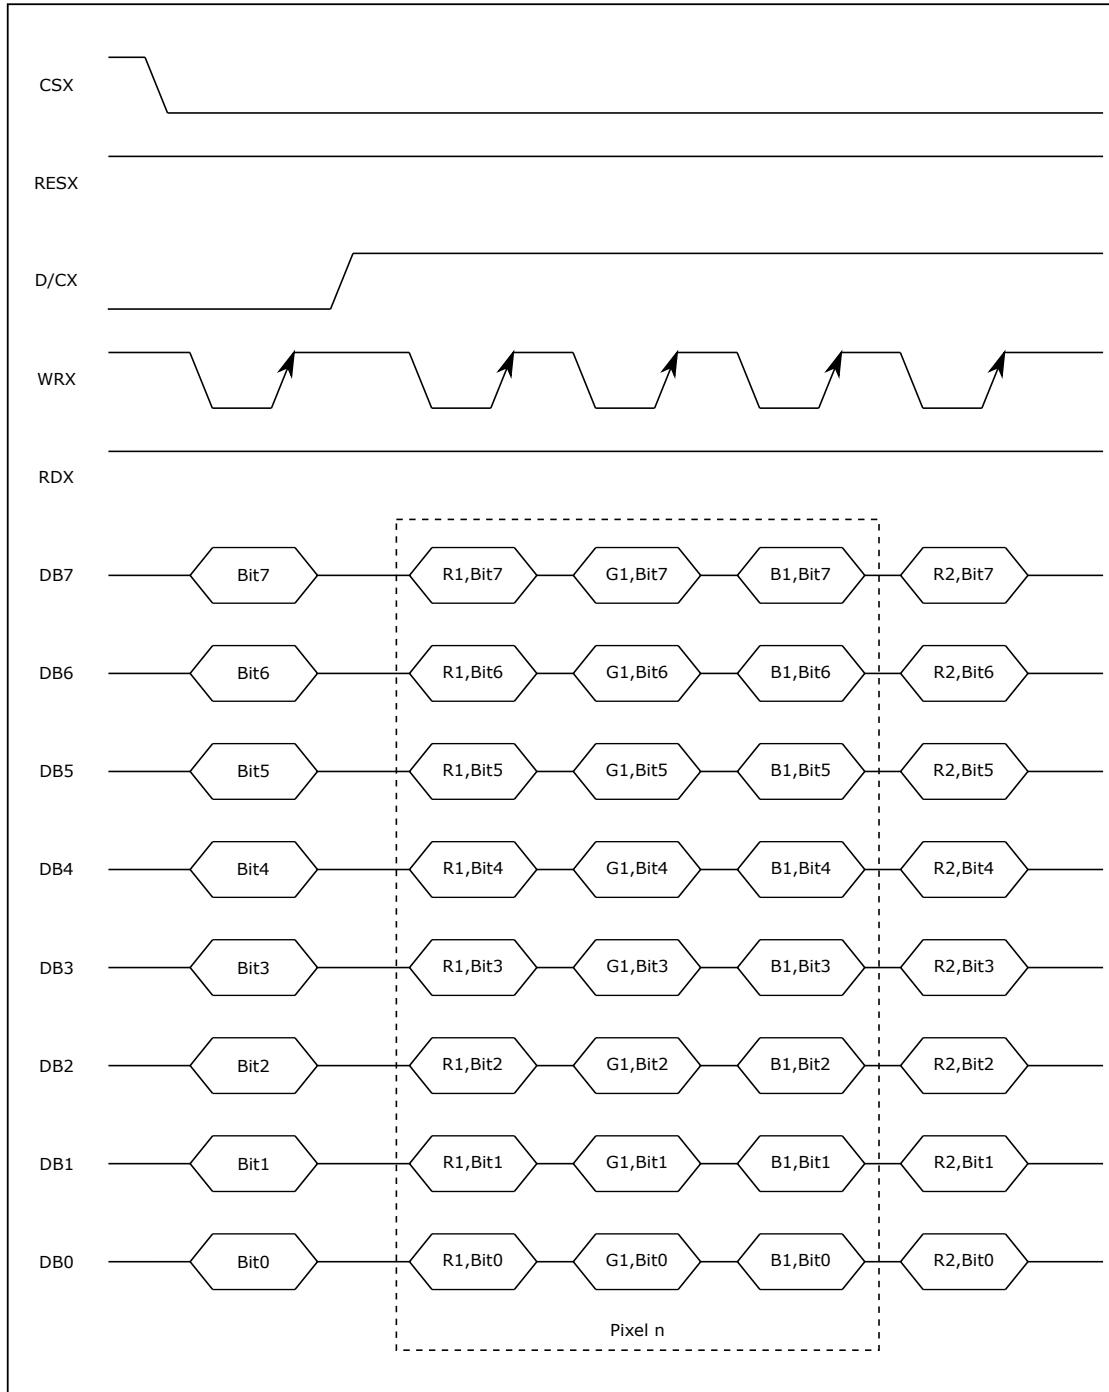

Fig. 10.6: RGB888 Output

10.3.2 DBI Type C 3-Line

10.3.2.1 Write Timing

The DBI Type C mode has 3-line 9-bit serial interface, and the timing of MCU writing data to the display module is shown as follows:

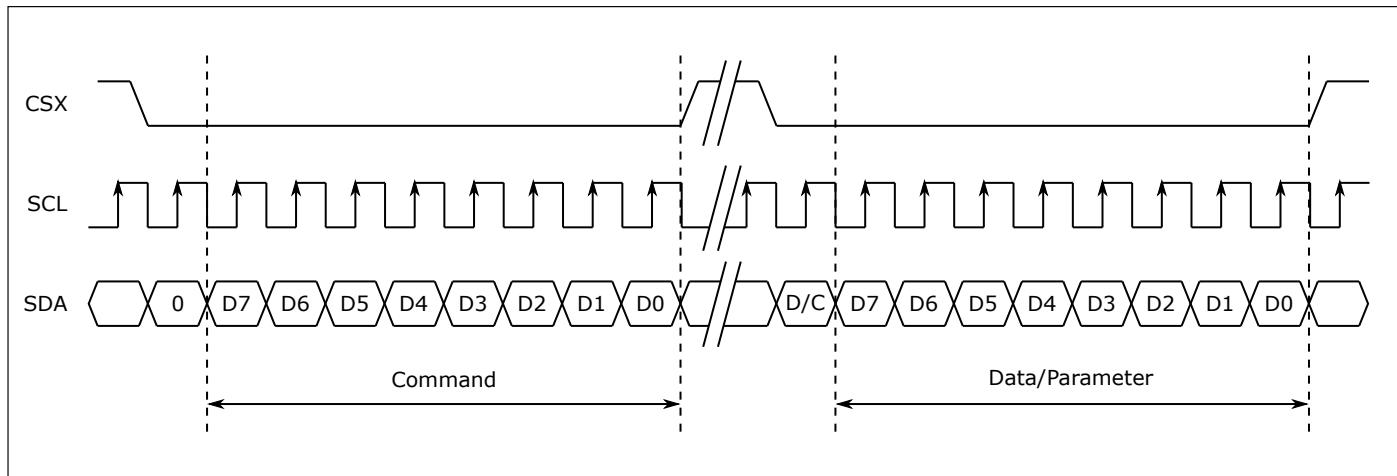

Fig. 10.7: Write Timing

- CSX: chip select signal. When the signal is Low, the display module will be selected; when it is High, the display module will ignore all other interface signals.
- SCL: serial clock line, which provides a clock signal for data transfer.
- SDA: serial data line. In a write operation, the serial data packet contains a D/CX (data/command) selection bit and a transfer byte. If the D/CX bit is Low, the transfer byte is a command. If the D/CX bit is High, that is the display data or command parameter.

10.3.2.2 Read Timing

The timing of MCU reading data from the display module is shown as follows:

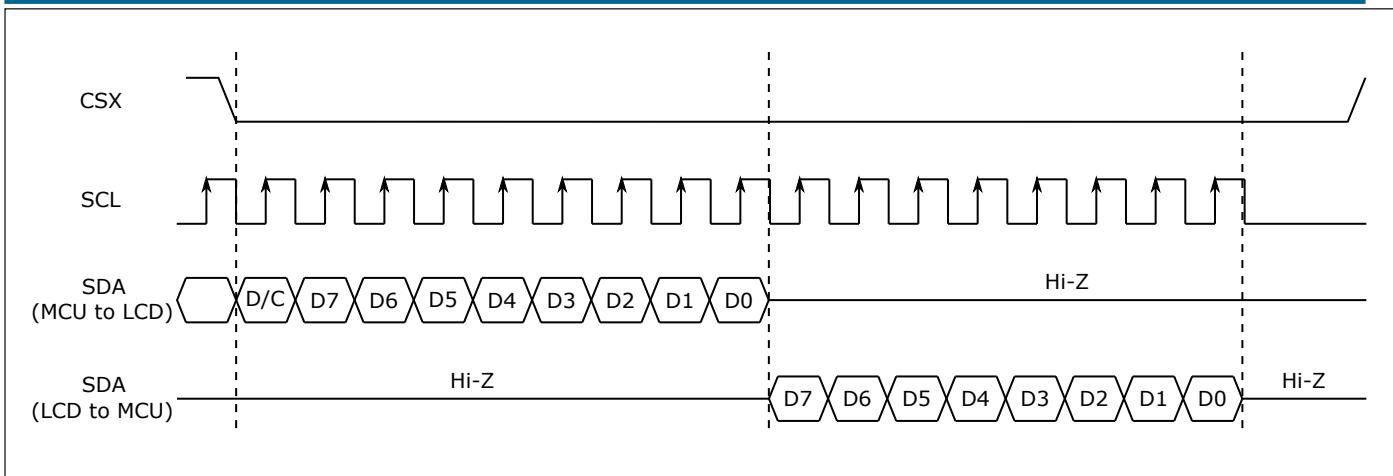

Fig. 10.8: Read Timing

10.3.2.3 Output RGB565

The data output in RGB565 format is shown as follows:

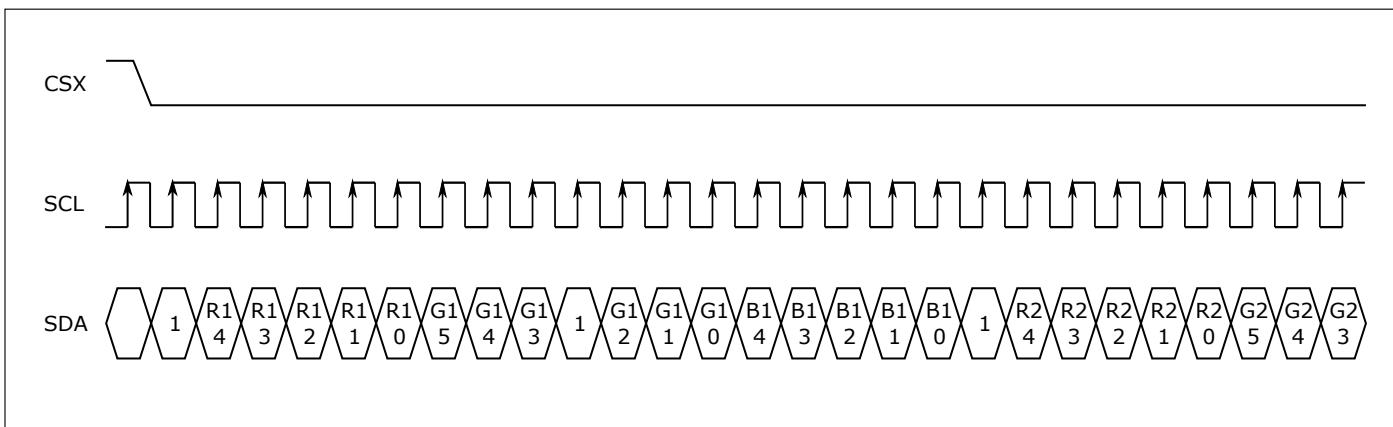

Fig. 10.9: RGB565 Output

10.3.2.4 Output RGB666

The data output in RGB666 format is shown as follows:

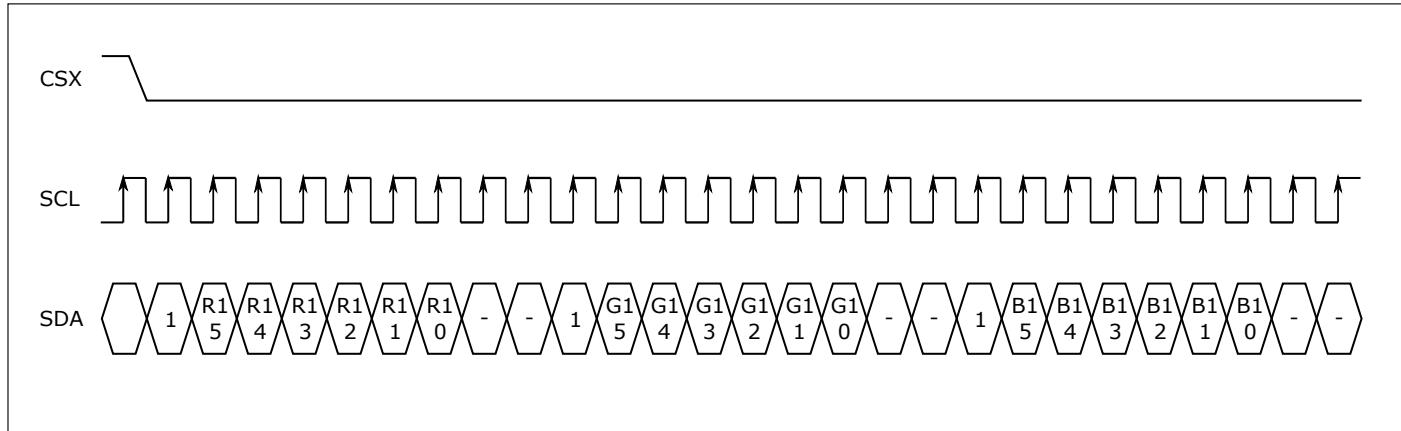

Fig. 10.10: RGB666 Output

10.3.2.5 Output RGB888

The data output in RGB888 format is shown as follows:

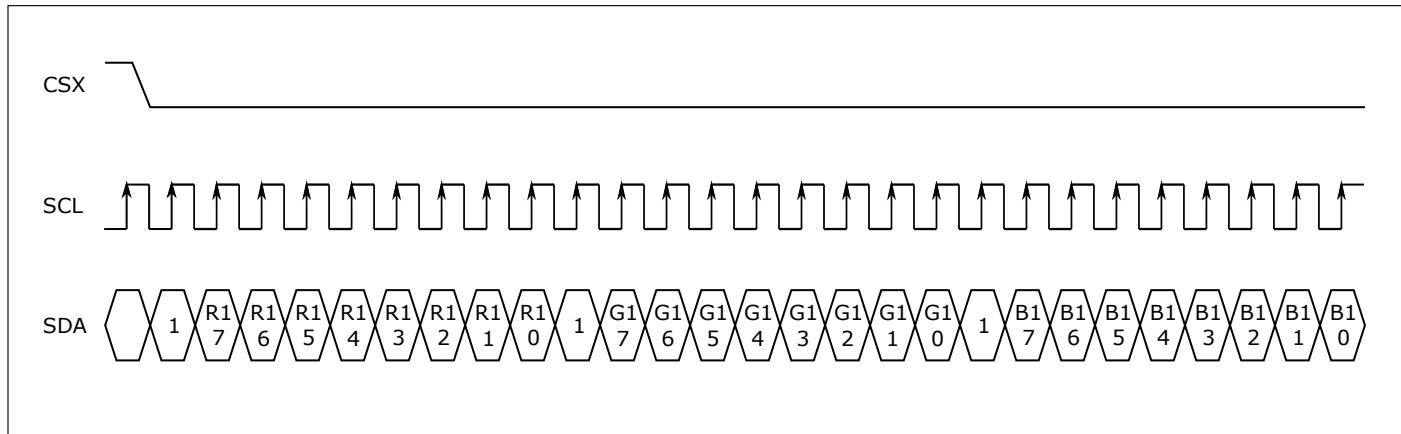

Fig. 10.11: RGB888 Output

10.3.3 DBI Type C 4-Line

10.3.3.1 Write Timing

The DBI Type C mode has 4-line 8-bit serial interface, and the timing of MCU writing data to the display module is shown as follows:

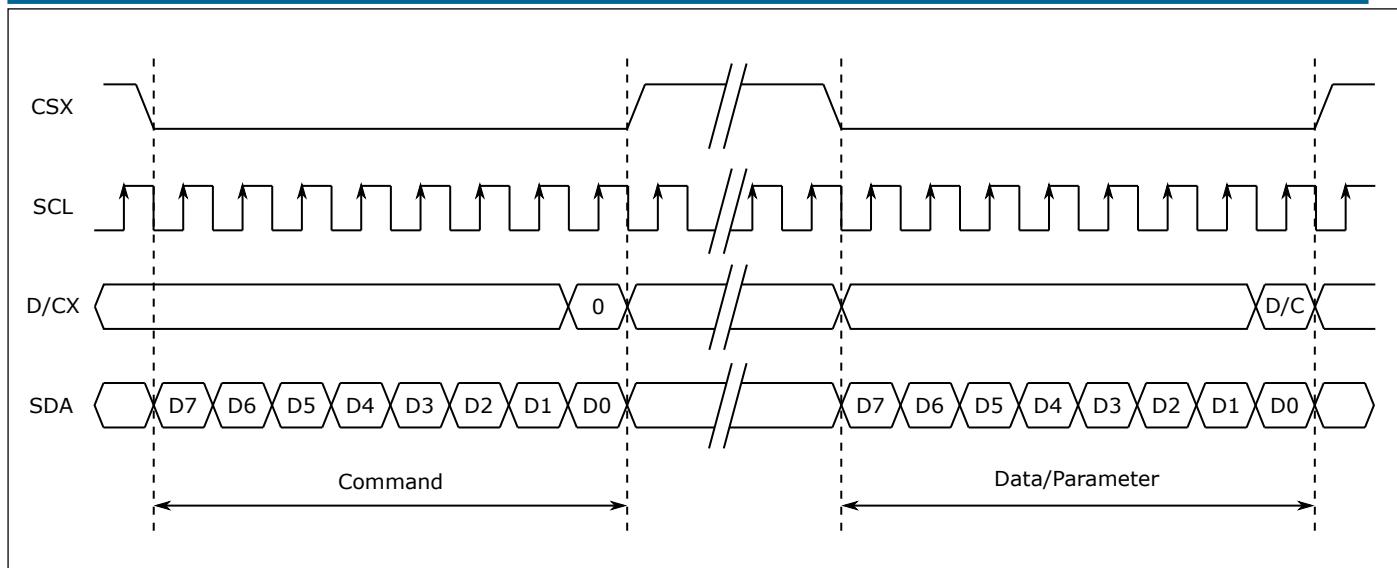

Fig. 10.12: Write Timing

- CSX: chip select signal. When the signal is Low, the display module will be selected; when it is High, the display module will ignore all other interface signals.
- D/CX: data/command signal. If the signal is Low, the information transferred by SDA is a command. If the signal is High, that is the display data or command parameter.
- SCL: serial clock line, which provides a clock signal for data transfer.
- SDA: serial data line. used to transmit commands, command parameters or data.

10.3.3.2 Read Timing

The timing of MCU reading data from the display module is shown as follows:

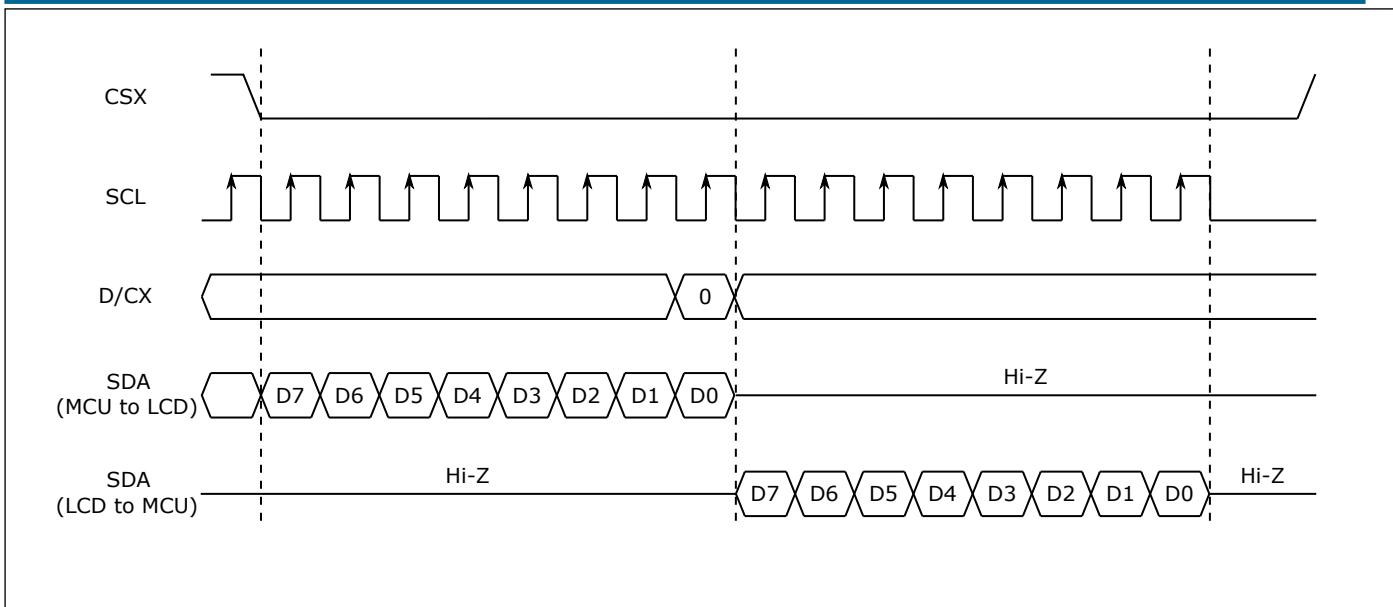

Fig. 10.13: Read Timing

10.3.3.3 Output RGB565

The data output in RGB565 format is shown as follows:

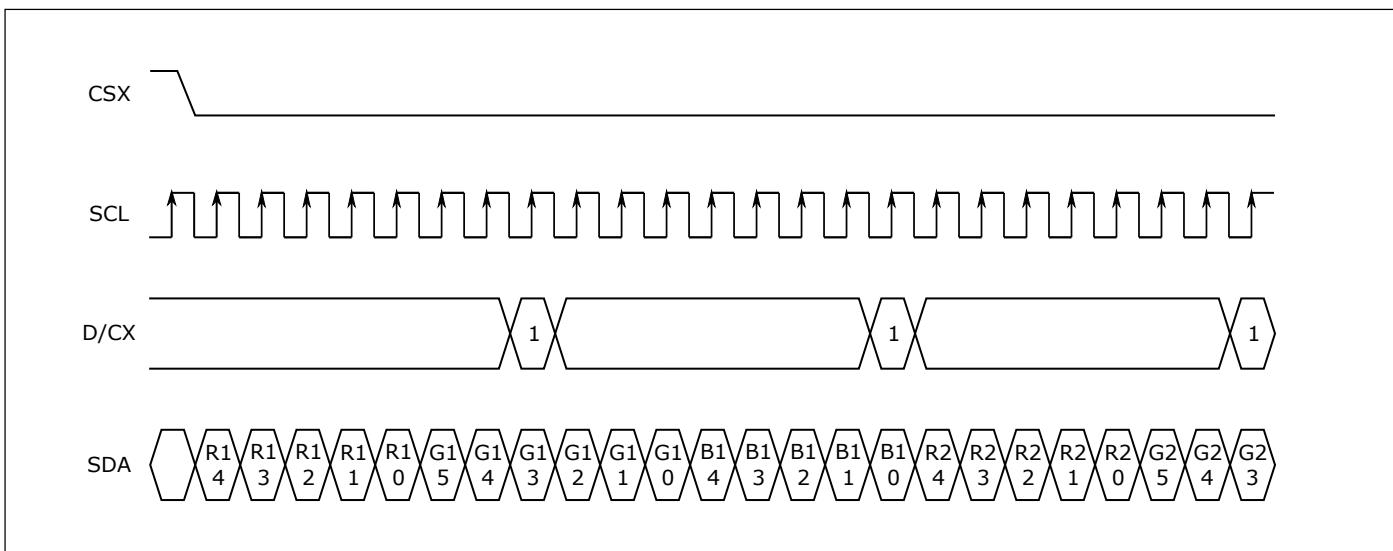

Fig. 10.14: RGB565 Output

10.3.3.4 Output RGB666

The data output in RGB666 format is shown as follows:

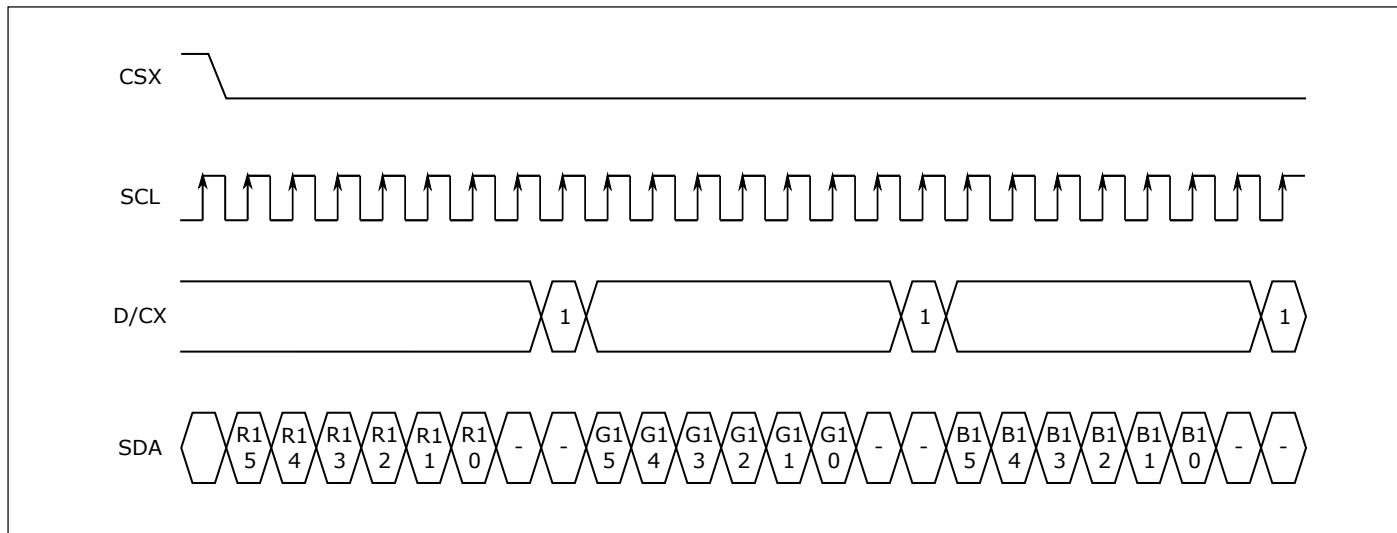

Fig. 10.15: RGB666 Output

10.3.3.5 Output RGB888

The data output in RGB888 format is shown as follows:

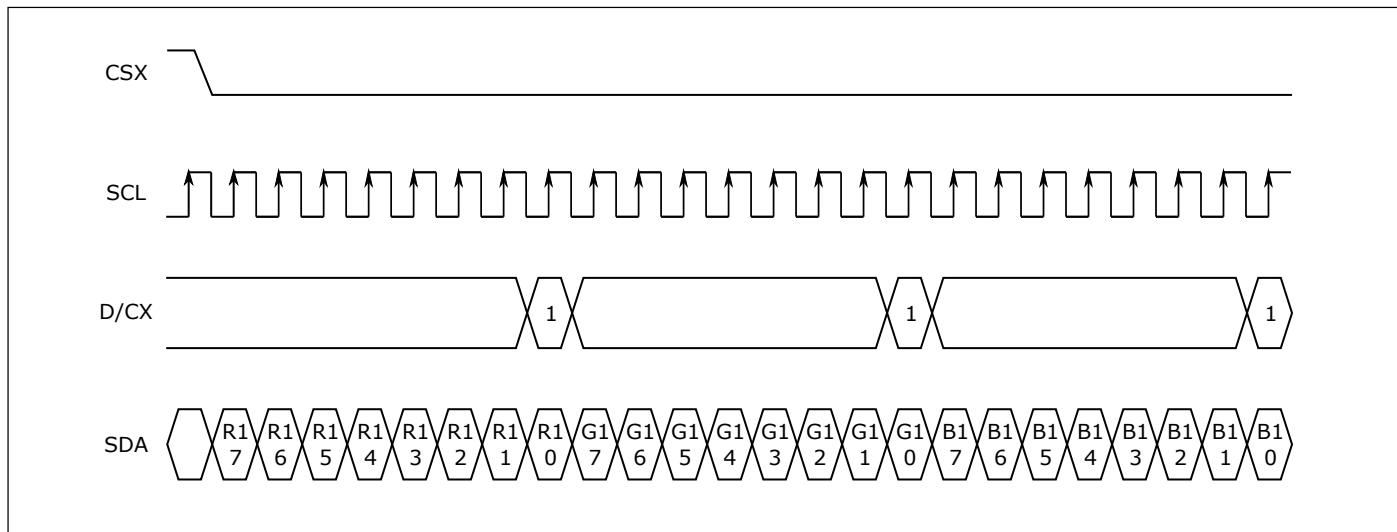

Fig. 10.16: RGB888 Output

10.3.4 Input Pixel Format

The DBI module supports 8 different input pixel formats, whose arrangement in the memory is shown as follows:

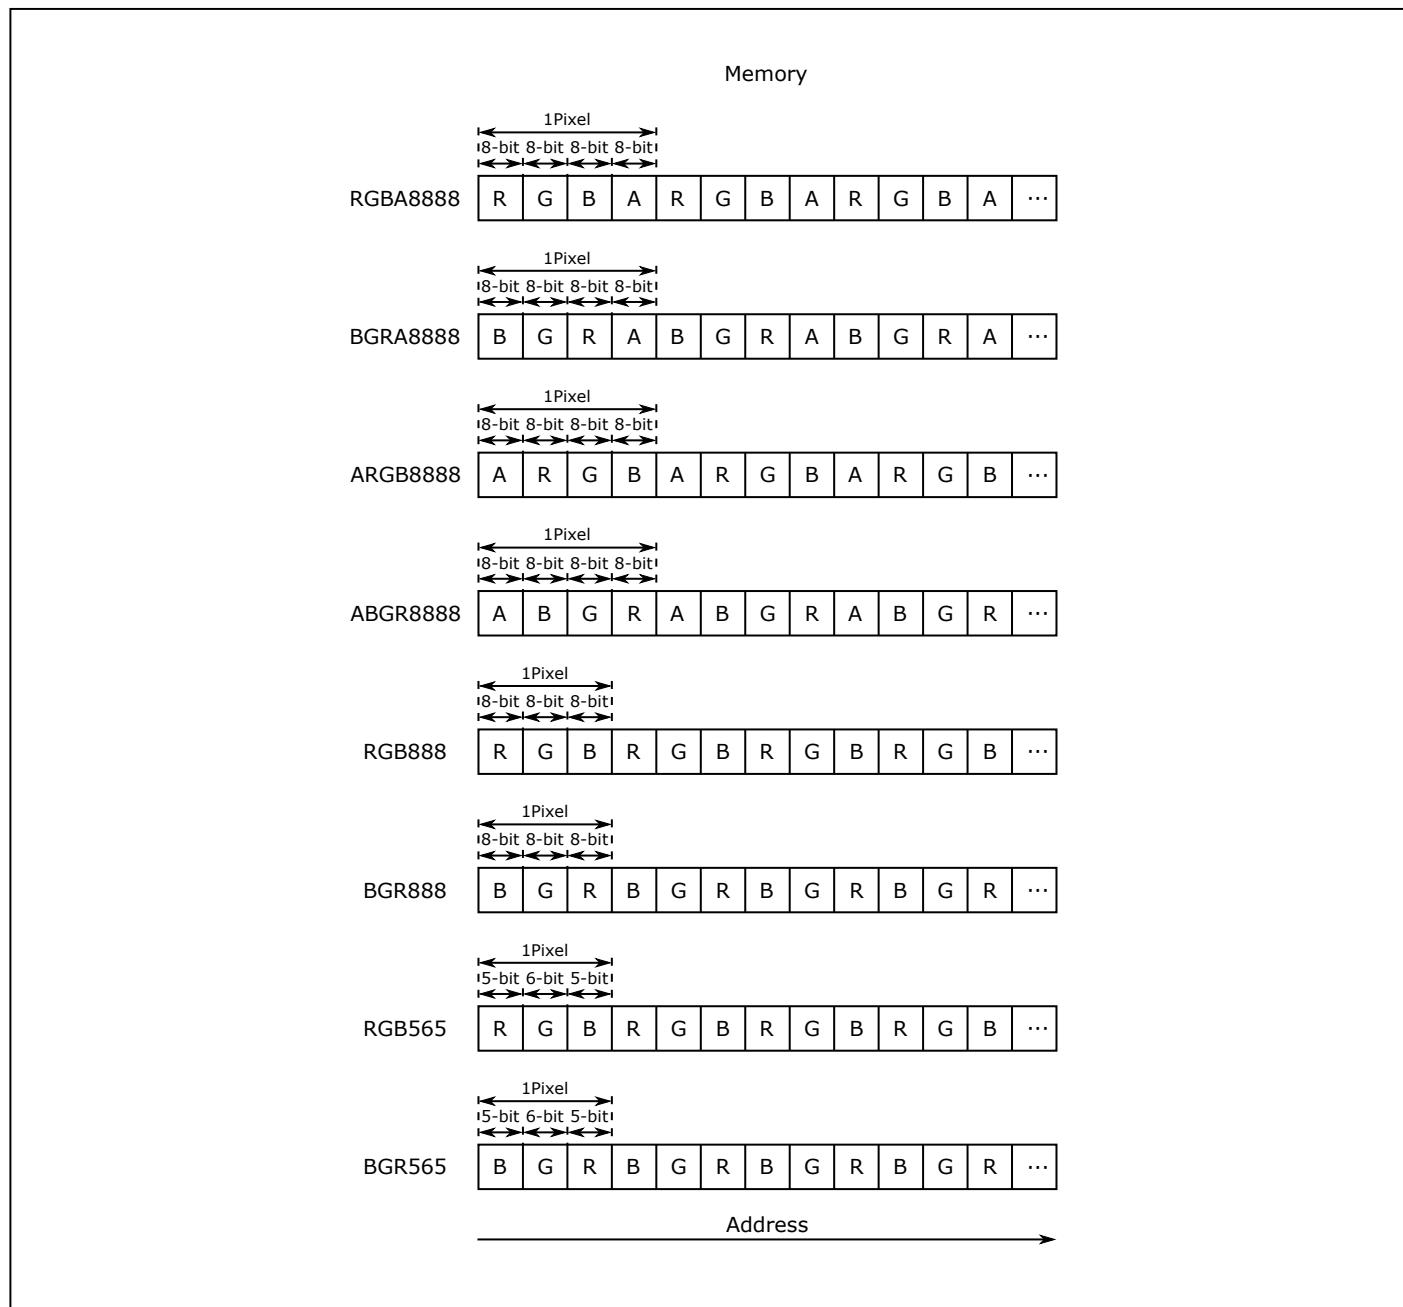

Fig. 10.17: Input Pixel Format

10.3.5 Interrupt

DBI has the following interrupts:

- End of transfer interrupt
- TX FIFO request interrupt
- FIFO overflow error interrupt

When a pixel count value is set, the end of transfer interrupt will be generated when the transferred pixel data reaches the count value, and both Type B and Type C will generate this interrupt.

When TFICNT in DBI_FIFO_CONFIG_1 is greater than TFITH, the TX FIFO request interrupt will be generated, and the interrupt flag will be automatically cleared when the condition is not met.

The FIFO overflow error interrupt will be generated in the case of Overflow or Underflow of TX.

10.3.6 DMA

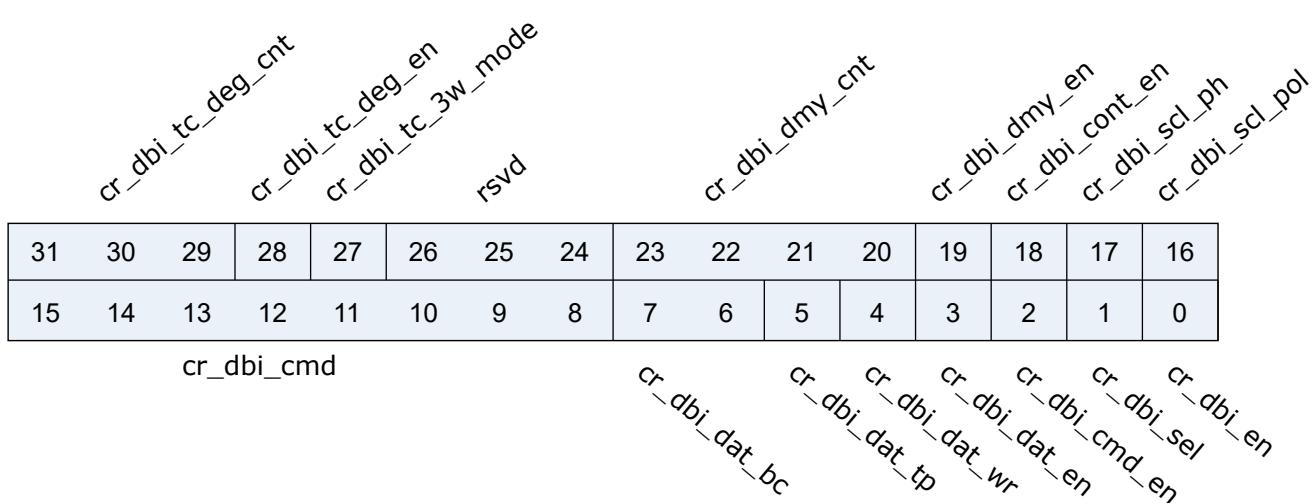

DBI TX supports the DMA transfer mode, which requires to set the threshold of TX FIFO by configuring the <TFITH> bit in the register DBI_FIFO_CONFIG_1. When this mode is enabled, if TFICNT is greater than TFITH, the DMA TX request will be triggered. After DMA is configured, when receiving this request, DMA will transfer data from memory to TX FIFO as configured.

DPI

11.1 Overview

The Display Pixel Interface (DPI), also known as RGB interface, is an interface protocol defined by MIPI Alliance for communicating with display screens. This module has 16-bit parallel data lines, with the system memory acting as the display memory, and drives the display directly by continuously outputting data and synchronization signals.

11.2 Features

- Meets MIPI® Alliance standard
- Supports single buffer and ping-pong buffer serving as the display memory
- Supports hardware and software control for ping-pong operation
- Supports the Test Mode
- Programmable timing parameters
- Supported input pixel format (buffer data format):
 - YUV422 (interleaved)
 - RGB888
 - RGB565
 - RGBA8888
 - YUV420 (planar)
- Supports output pixel format of RGB565
- One programmable interrupt
- Use with OSD

11.3 Functional Description

The block diagram of DPI Module is shown as follows.

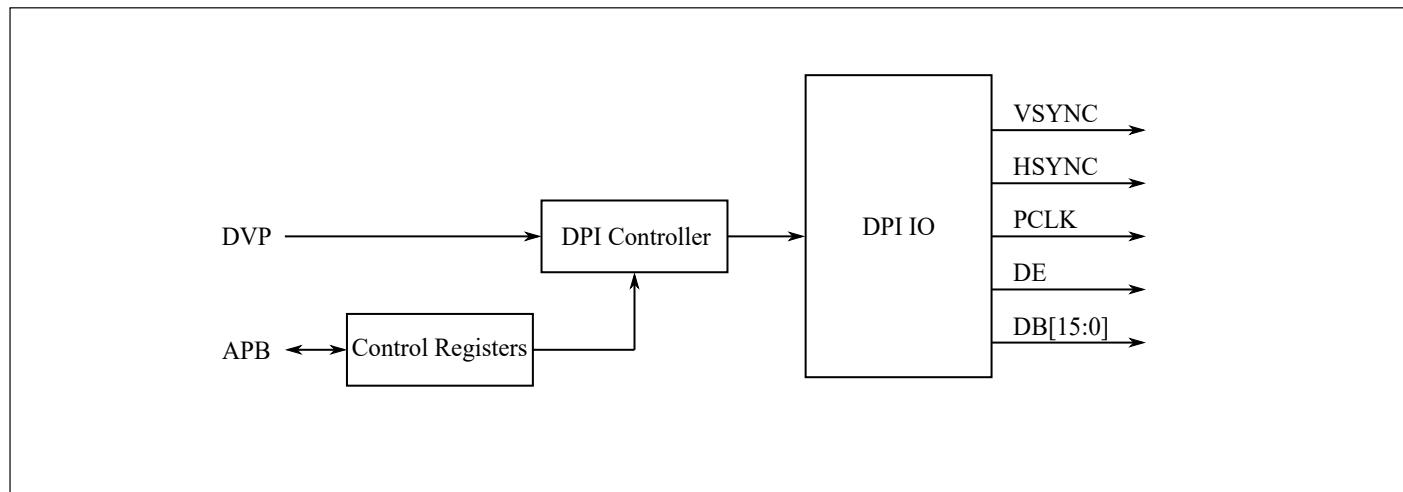

Fig. 11.1: Block Diagram of DPI

11.3.1 DPI Timing

The 16-bit DPI interface timing is shown as follows:

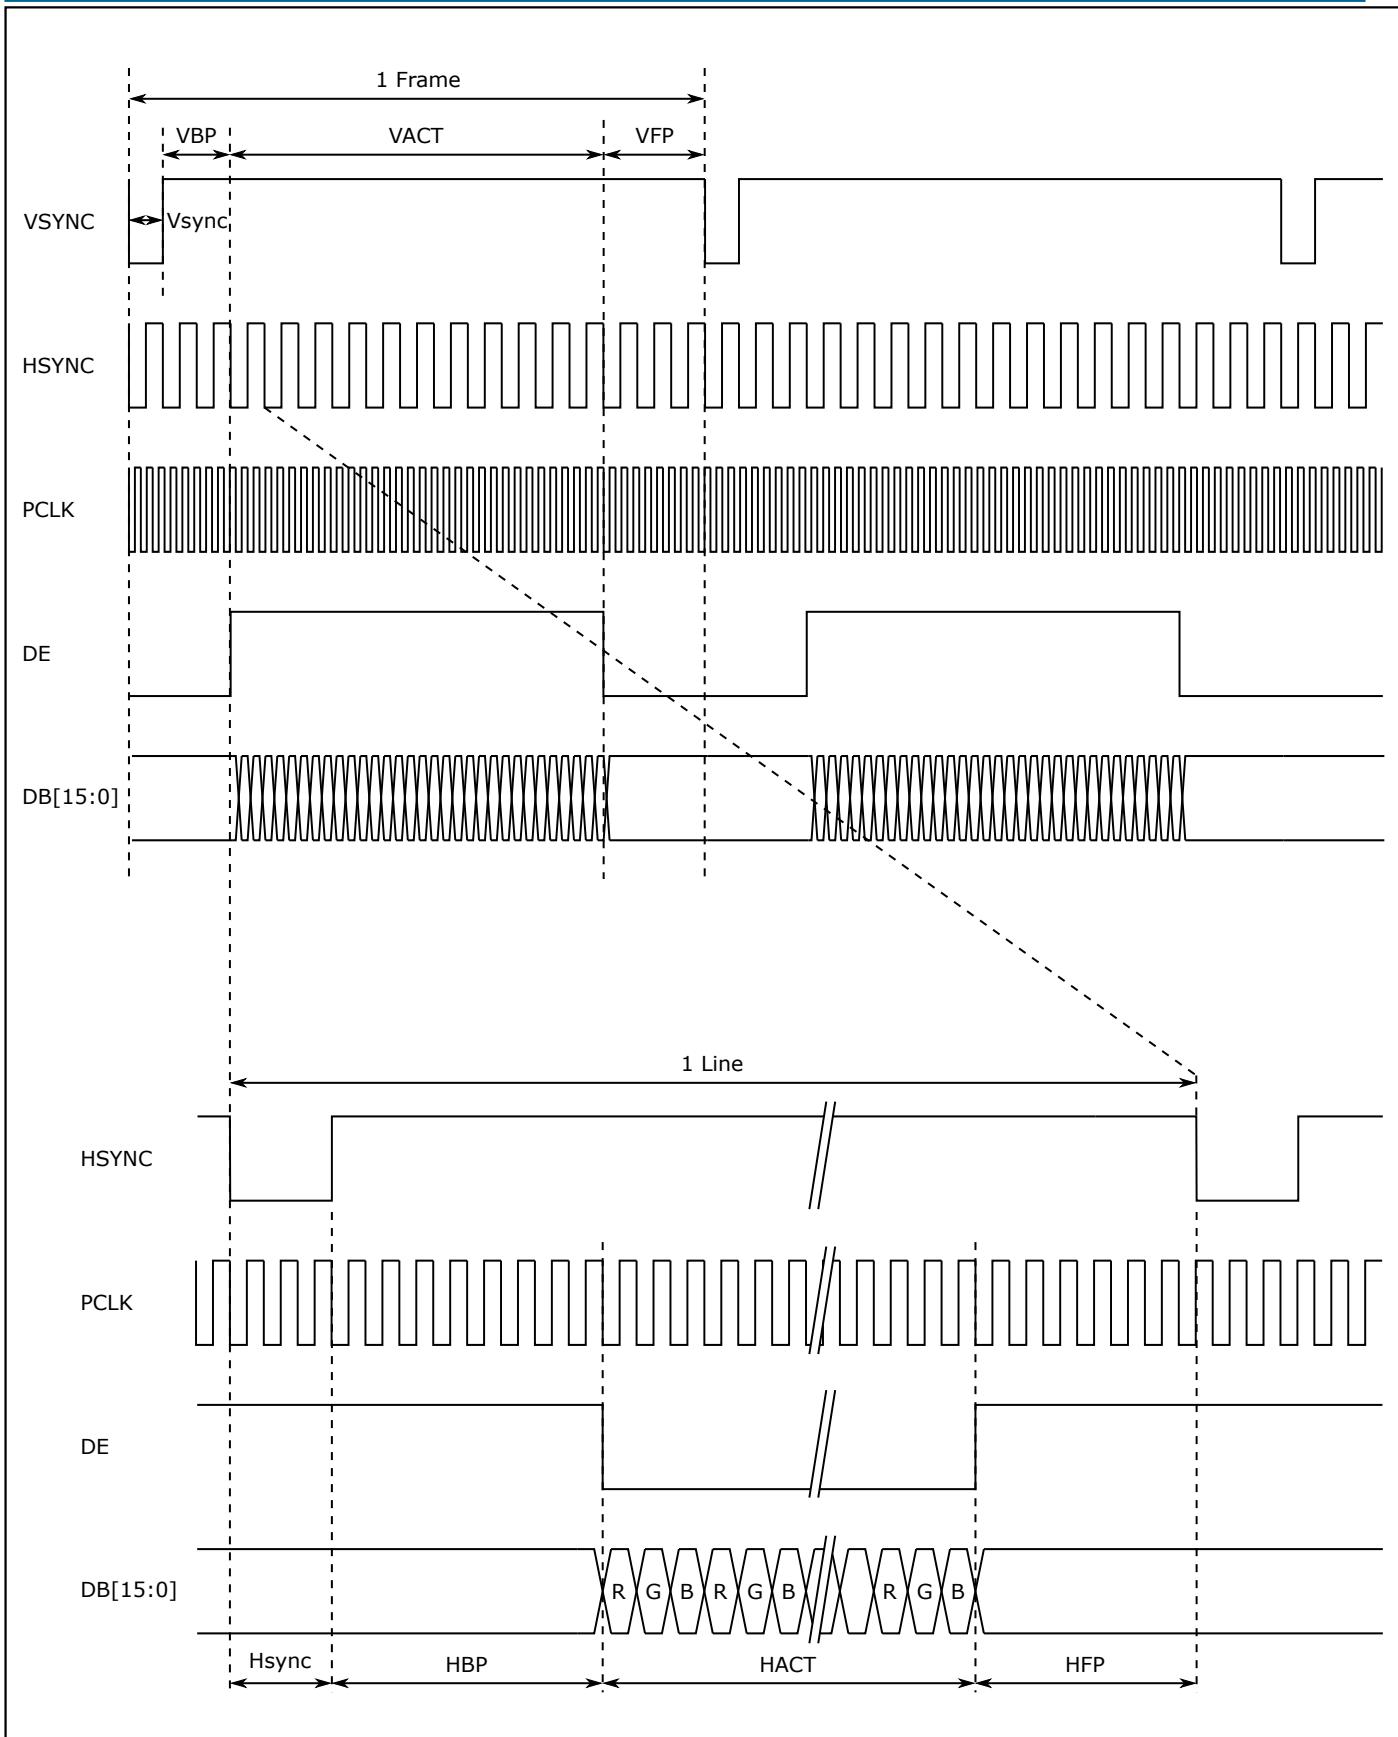

Fig. 11.2: DPI Timing

- Vertical Sync (VSYNC): Vertically synchronized timing signal, used to indicate the beginning of each displayed image frame
- Horizontal Sync (Hsync): Horizontally synchronized timing signal, used to indicate the beginning of each horizontal pixel line
- Pixel Clock (PCLK): Pixel clock, continuously generated; VSYNC, HSYNC, DE, and DB [15:0] will be sampled at the rising edge of PCLK
- Data Enable (DE): Data enable signal, used to indicate valid pixel data
- Data Bit (DB) [15:0]: Parallel data bits -16 bits in total, used to transfer pixel data.

11.3.2 Programmable timing parameters

The timing parameters of DPI are shown as follows:

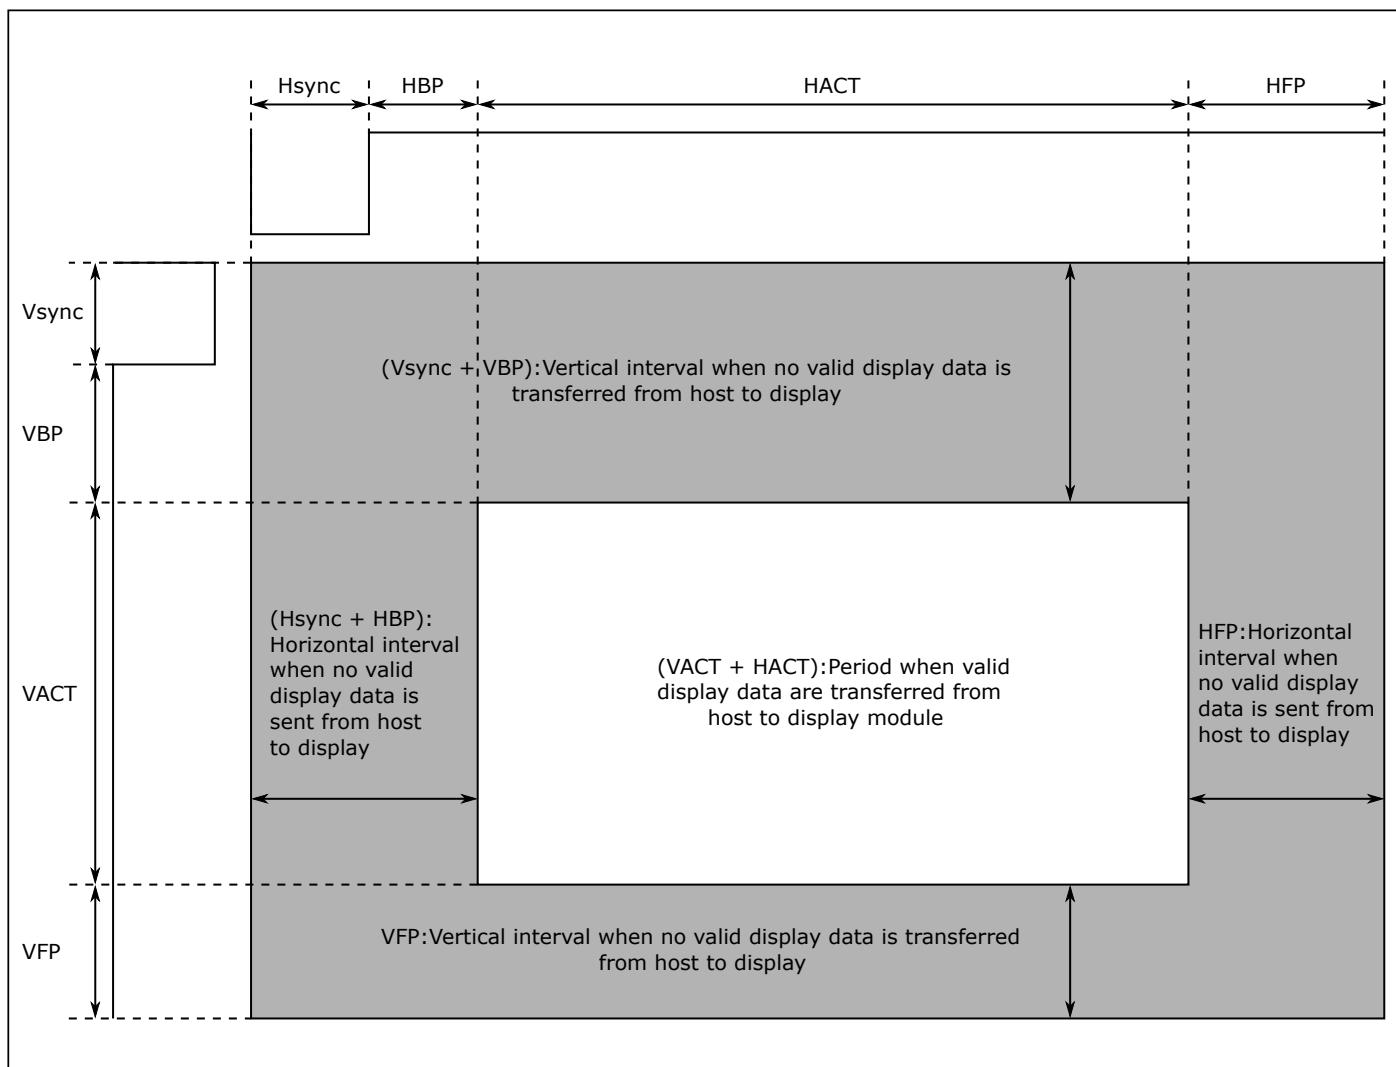

Fig. 11.3: Timing Parameters

The vertical period (one frame) is equal to the sum of Vsync, VBP, VACT, and VFP. The horizontal period (one line) is equal to the sum of Hsync, HBP, HACT, and HFP. The programmable ranges of the timing parameters are shown in the following table:

Parameters	Symbols	Min.	Step	Max.	Unit
Horizontal Synchronization	Hsync	1	1	255	PCLK Cycle
Horizontal Back Porch	HBP	1	1	-	PCLK Cycle
Horizontal Active	HACT	176	1	800	PCLK Cycle
Horizontal Front Porch	HFP	1	1	255	PCLK Cycle
Vertical Synchronization	Vsync	1	1	255	Line
Vertical Back Porch	VBP	1	1	-	Line
Vertical Active	VACT	208	1	480	Line
Vertical Front Porch	VFP	1	1	255	Line

Fig. 11.4: Ranges of Timing Parameters

11.3.3 Single Buffer

The DPI Module can use one memory with a size of “display resolution × number of bytes per pixel” as the display memory. When it starts working, DPI transfers the data in this memory to the Display Module repeatedly and continuously. If changes are made to the data in this memory, the changes may take effect on the current or next frame, depending on whether the changed data is located in memory after or before the location in memory of the data currently being transferred by the DPI.

11.3.4 Ping-Pong Buffer

The DPI Module can use two memories with each size of “display resolution × number of bytes per pixel” as the display memory. DPI transfers the data in one memory to the Display Module repeatedly and continuously. The control mode for switching the current memory for data transfer to the other memory can be set to hardware or software control. When it is set to hardware control, the data for DPI is provided by the Cam Module (see Cam Module section); DPI switches the current memory in use to another memory after the Cam Module has written a complete frame of data to the memory not involved in transfer, and the data in the current memory is completely transferred. When it is set to software control, the memory currently used by DPI for transfer is set by <SWAP_IDX_SWV>, with “0” and “1” corresponding to two memory blocks respectively.

11.3.5 Test Mode

In Test Mode, DPI can output images with the same pixel color in the same row and a gradient color between different rows. The Test Mode requires three parameters, namely the minimum value of pixel data VAL_MIN (16 bit), the maximum value of pixel data VAL_MAX (16 bit), and the step size STEP (8 bit). DPI uses VAL_MIN as the value of each pixel in the 1st row, (VAL_MIN+STEP) as the one in the 2nd row, and (VAL_MIN+STEP*2) as the one in the 3rd row...and so on, and returns to VAL_MIN when the pixel value of the Nth row (VAL_MIN+STEP*(N1)) is greater than VAL_MAX. This cycle repeats until the number of output rows reaches the set value. Taking VAL_MIN=0x00E0, VAL_MAX=0x012F, and STEP=0x10 as an example, the display in the Test Mode is shown as follows:

VAL_MIN=0x00E0, VAL_MAX=0x012F, STEP=0x10

Fig. 11.5: Test Mode

11.3.6 Input Pixel Format

DPI supports input in multiple pixel formats. Internally, it will convert these formats to RGB888 uniformly and then convert RGB888 to RGB565 for sending out.

11.3.6.1 YUV422 (Interleaved)

The processing of input data in YUV422 (interleaved) format is shown as follows:

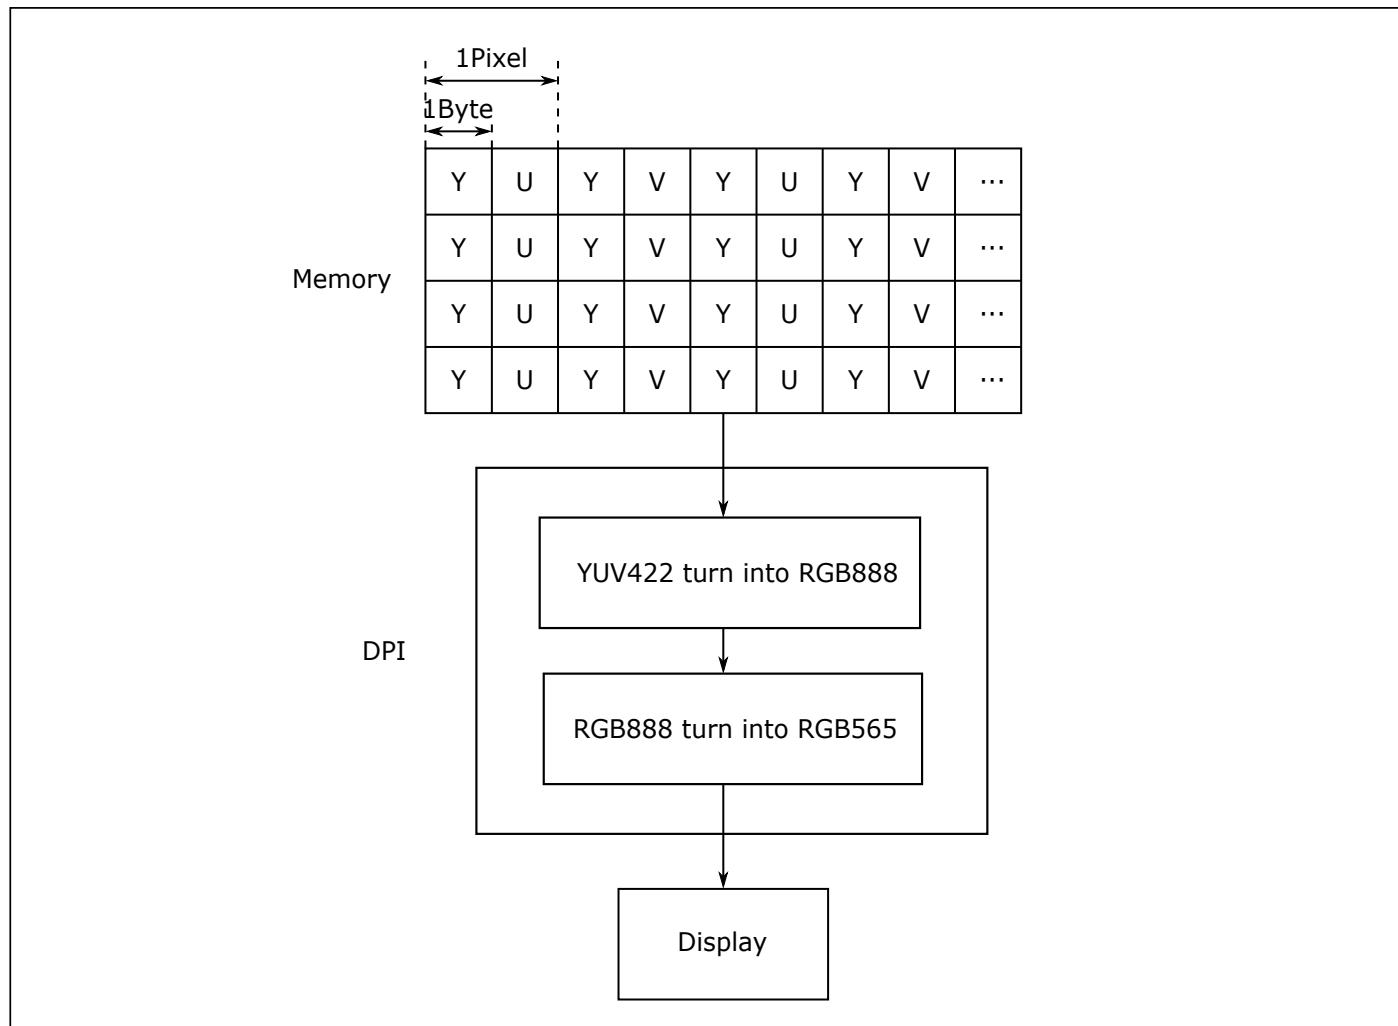

Fig. 11.6: YUV422 Processing Process

11.3.6.2 RGB888

The processing of input data in RGB888 format is shown as follows:

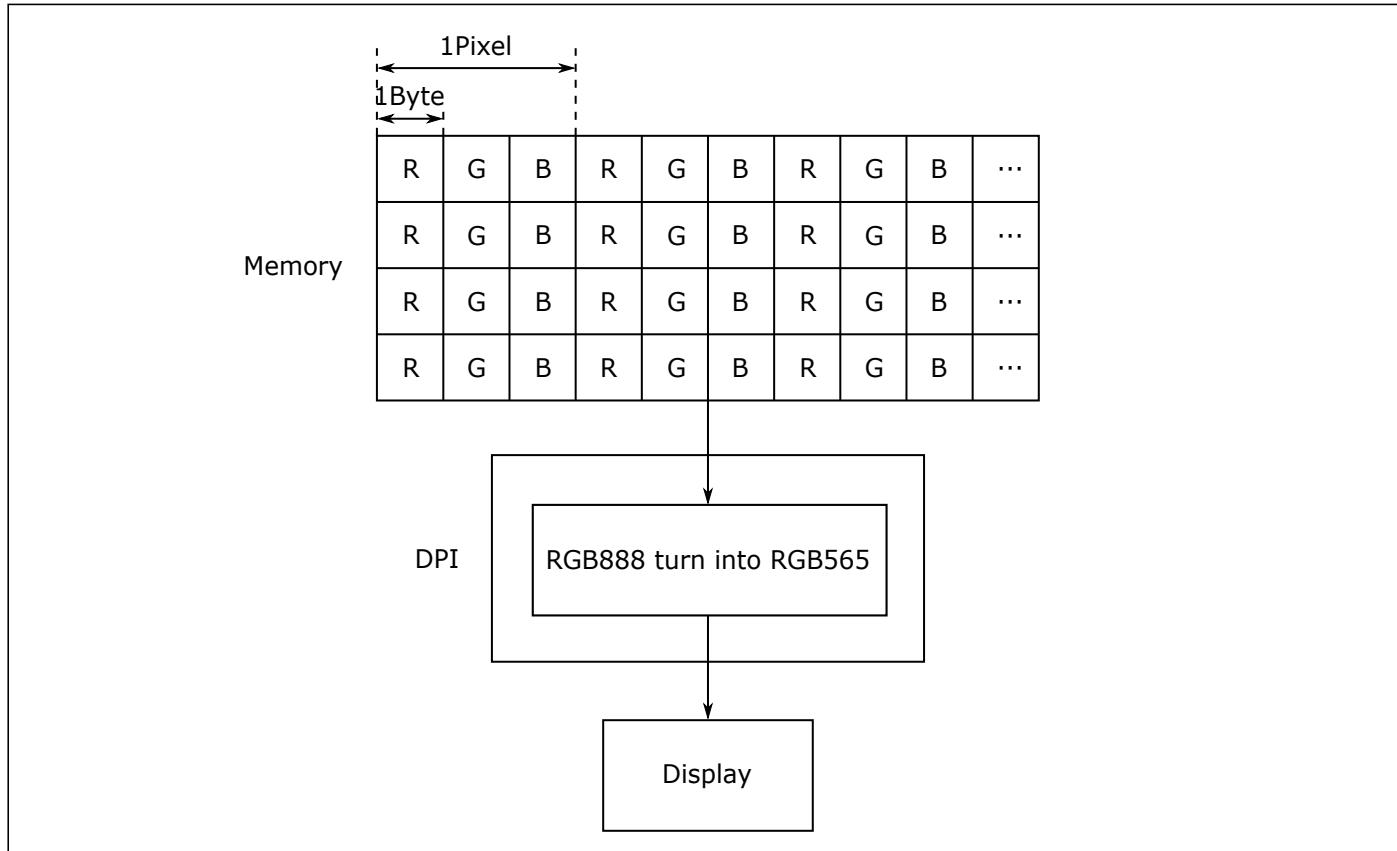

Fig. 11.7: RGB888 Processing Process

11.3.6.3 RGB565

The processing of input data in RGB565 format is shown as follows:

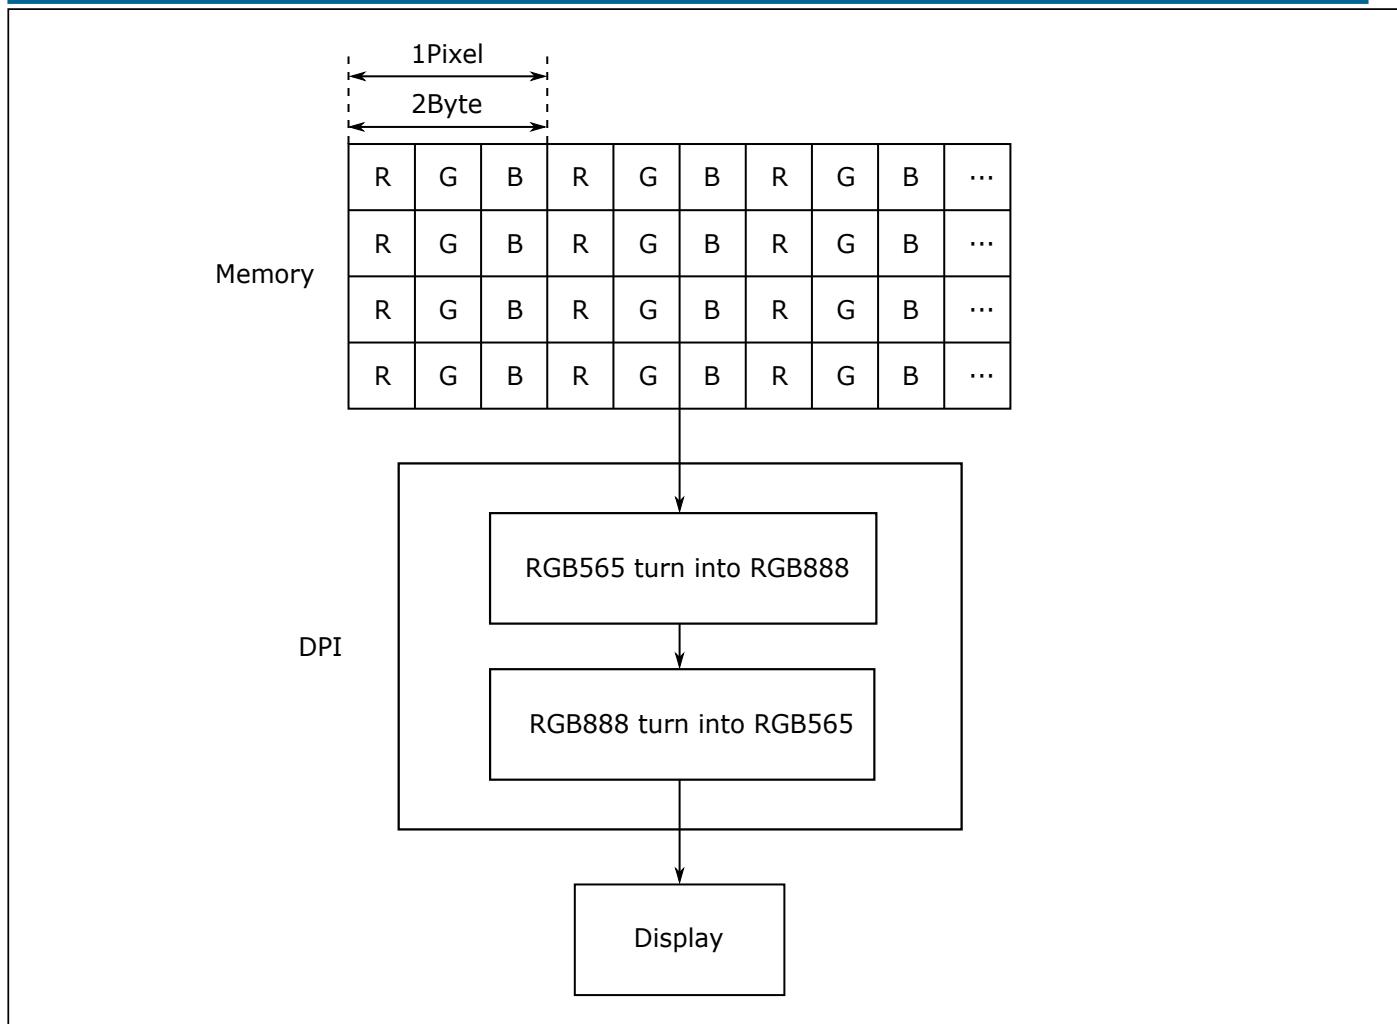

Fig. 11.8: RGB565 Processing Process

11.3.6.4 RGBA8888

The processing of input data in RGBA8888 format is shown as follows:

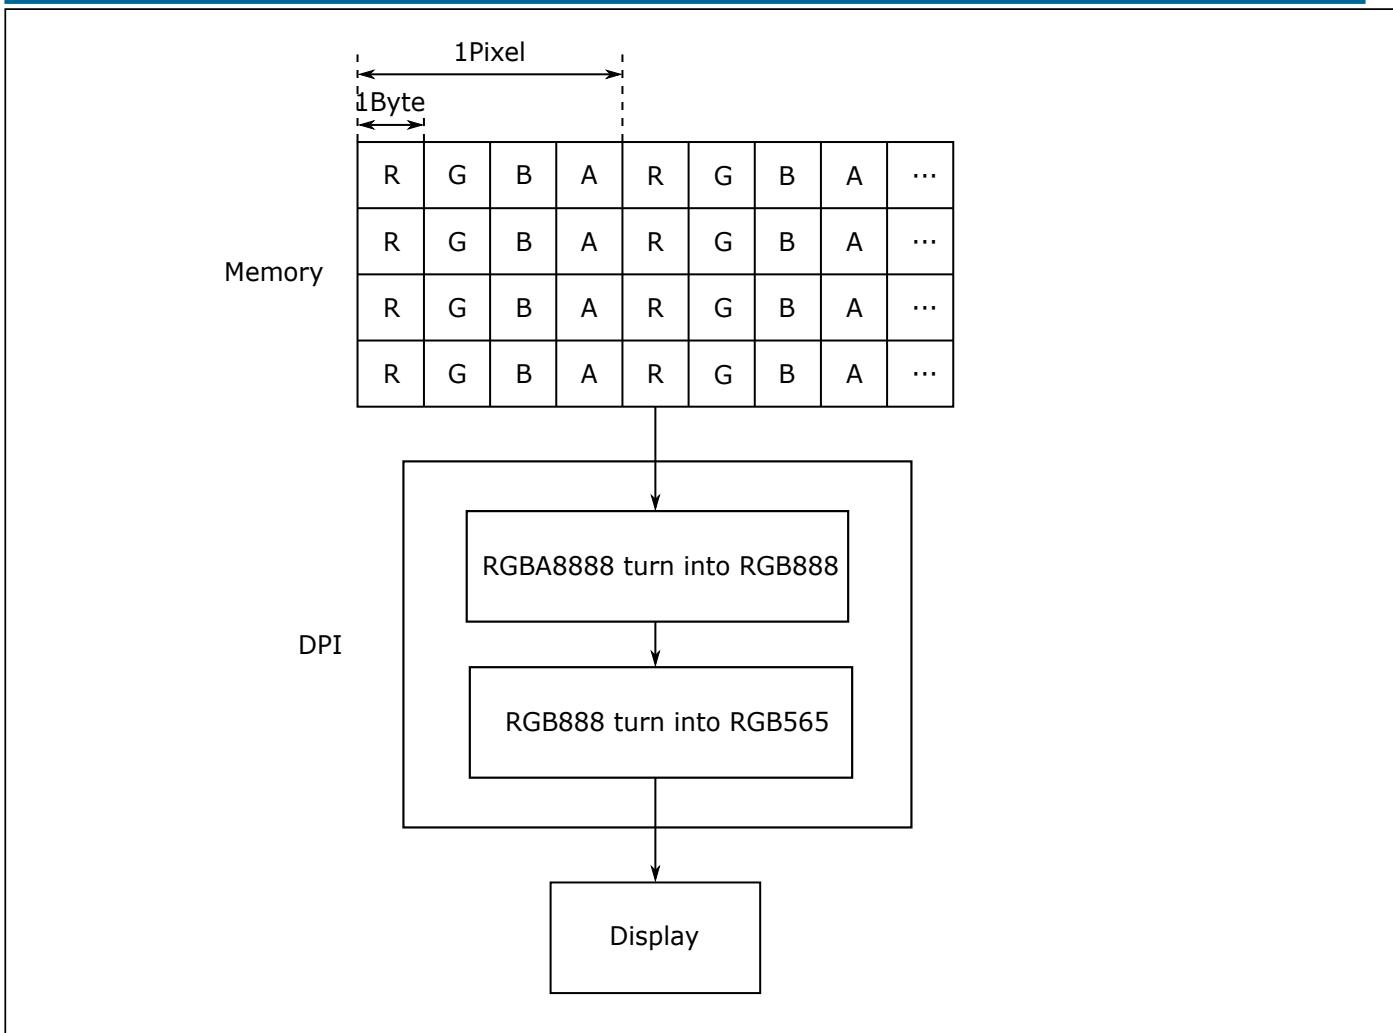

Fig. 11.9: RGBA8888 Processing Process

11.3.6.5 YUV420 (Planar)

The processing of input data in YUV420 (planar) format is shown as follows:

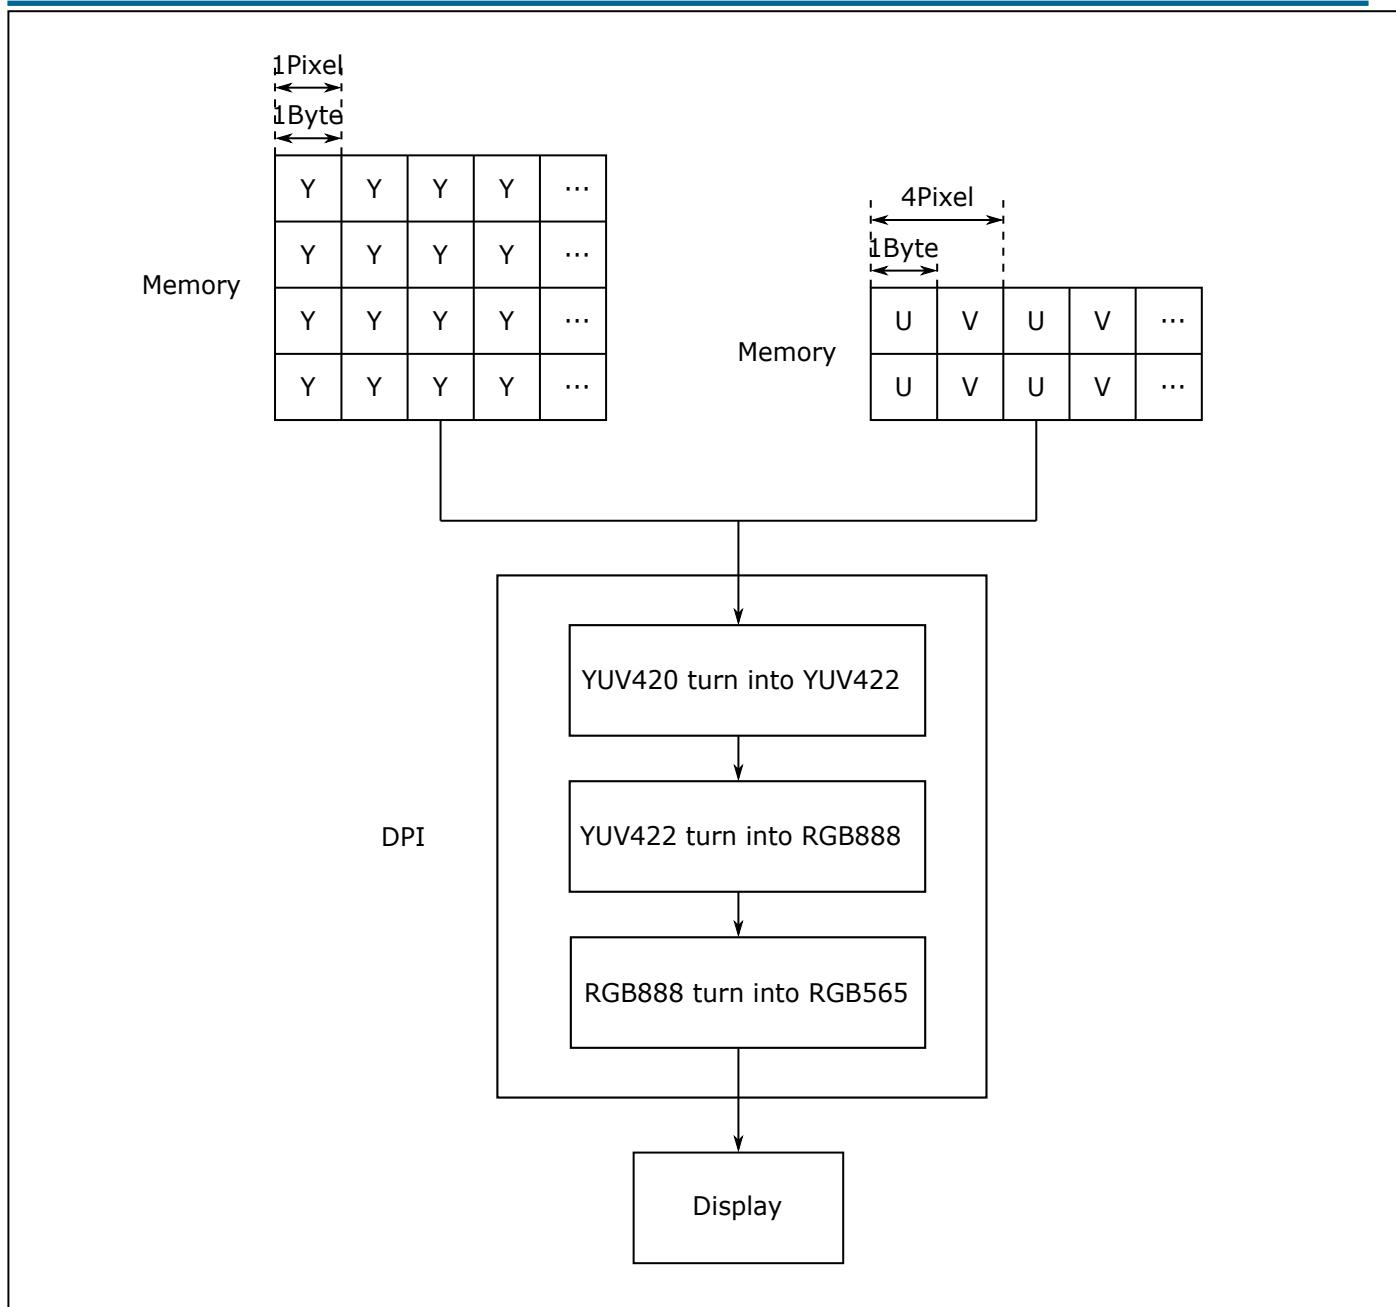

Fig. 11.10: YUV420 Processing Process

11.3.7 Programmable Interrupt

The DPI has a programmable interrupt. In configuration, the trigger source of the interrupt can be set to the input Vsync or output Vsync of the DPI, and the hopping edge can be the rising or falling edge. For example, if the interrupt is configured to be triggered on the rising edge of the input Vsync, DPI will generate an interrupt request on each Vsync rising edge of its input module. If that is configured to be triggered on the falling edge of the output Vsync, DPI generates an interrupt request on each Vsync falling edge of its output module.

11.3.8 Use with OSD

The input data of DSI can be configured to be processed by the OSD first. See the OSD Module section for functional description.

12

DSI

12.1 Overview

The Display Serial Interface (DSI) is an interface protocol defined by MIPI Alliance for communicating with display screens. It sends pixels or commands to peripherals and can read status or pixel information from peripherals. All data lanes of DSI are unidirectional in High-Speed Mode, while in Low-Speed Mode only the first data lane is bidirectional and other lanes are unidirectional. The clock lane is dedicated to transmitting synchronous clock signals during high-speed data transmission. In addition, one master side allows communication with multiple slave sides at the same time. This chip has a built-in DSI controller and DPHY, which enable communication with DSI-compatible displays so that data can be displayed on the screen.

12.2 Features

- Meets MIPI® Alliance standard
- MIPI® DPHY interface with maximum speed of 800 Mbps
- One Clock Lane, up to 4 Data Lanes
- Four sequences for Data Lanes
- Supports Ultra Low Power Mode and High Speed Mode
- Data Lane 0 supports bidirectional communication and Escape Mode
- Supports LPDT/ULPS/Trigger in the Escape Mode
- Supports short and long packet sending in the LPDT Mode
- Supports error correction code (ECC) and check function
- Supports data length error and data overflow error interrupt
- Supports Command Mode and Video Mode
- Supports Event and Pulse Modes in the Video Mode

- Data formats supported by the display interface:
 - YUV422, 8 bit
 - RGB565
 - RGB666, loosely packed
 - RGB888
- Rich and diverse interrupt mechanisms and status query
- Supports DMA transmission in the LPDT Mode
- Use with OSD

12.3 Functional Description

The block diagram of the DSI Module is shown as follows:

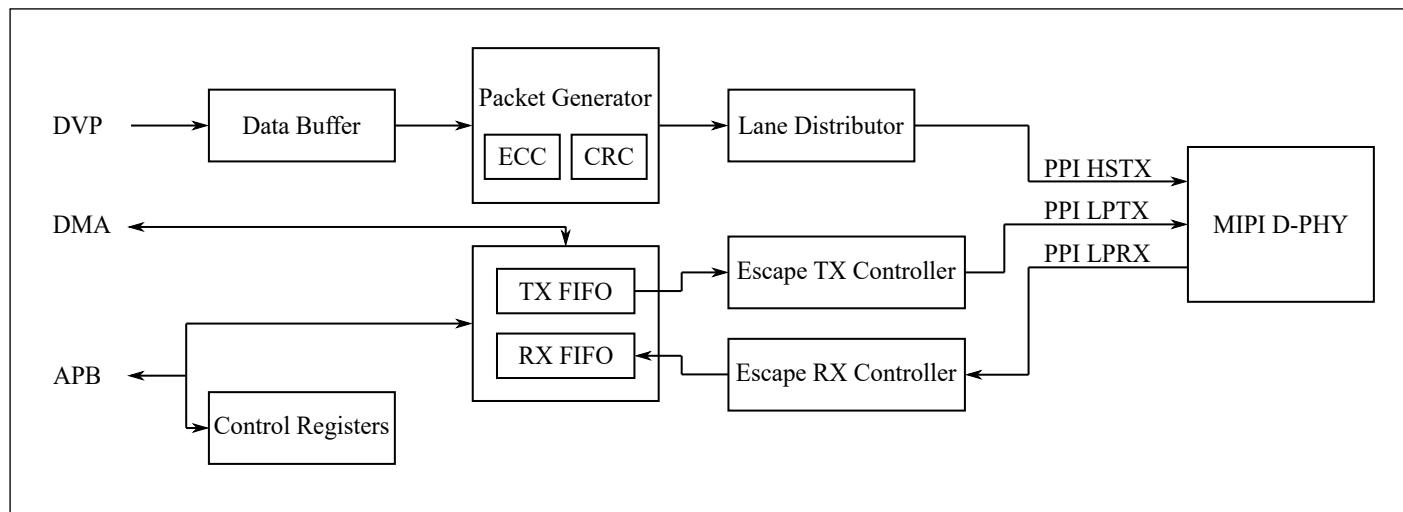

Fig. 12.1: Block Diagram of DSI

12.3.1 DSI Protocol Layering

The DSI protocol is divided into 4 layers from bottom to top, namely, physical layer, lane management layer, protocol layer, and application layer, as shown below:

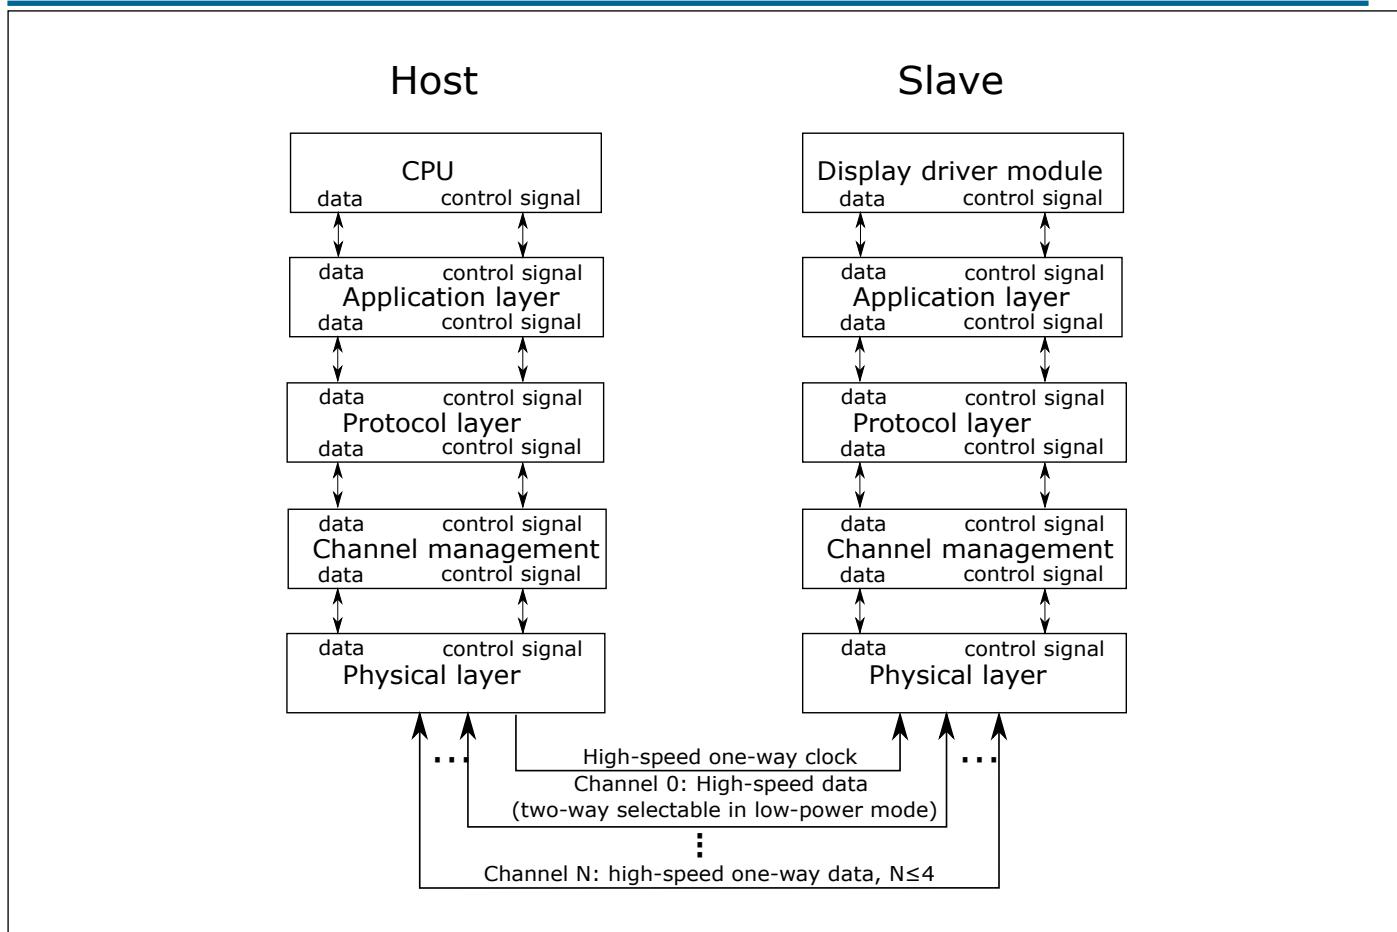

Fig. 12.2: Protocol Layering

Physical layer: It specifies the transmission medium (electrical conductor), the input/output circuit, and the clock mechanism for capturing “1” and “0” from the serial bit stream. In addition, it also specifies the signaling mechanism of start of transmission (SoT) and end of transmission (EoT) and other “out-of-band” information that can be transmitted between transmitting and receiving PHY.

Lane management layer: DSI can expand lanes to improve performance. The number of data lanes can be 1, 2, 3 or 4 depending on the bandwidth requirements of the application. The lane management layer aims to transfer the to-be-sent data from the transmitter (TX) end to the corresponding data lanes by groups according to the lane order, collect the data from each lane at the receiver (RX) end, and then merge them into a recombined data stream, thus recovering the original stream sequence.

Protocol layer: The DSI protocol defines packet formats, including short and long packets. The protocol layer aims to pack packets at the TX end according to the type and content of data, add the ECC and CRC codes, and transmit them to the lane management layer. At the RX end, it checks and corrects the received packet based on the ECC and CRC codes, decodes the packet header and data content, and transmits them to the application layer.

Application layer: Depending on the needs of application modules, at the TX end, it initially encodes the to-be-sent commands and data and converts them into the format specified by DSI; at the RX end, it restores the received data to the data format and timing supported by application modules.

12.3.2 Physical Layer

According to the DPHY protocol, synchronous connection is used between the master and the slave in the physical layer. The clock lane is used to transmit high-speed clocks, and one or more data lanes are used to transmit low-power or high-speed data signals. Each lane uses two interconnected lines to connect the master and the slave, and supports both High-Speed (HS) and Low-Power (LP) Modes. In the HS Mode, TX simultaneously drives two interconnected lines of the lane to output a low-swing differential signal, such as 200 mV. In the LP Mode, TX drives the interconnected lines respectively, to output a single-ended signal with a relatively large swing respectively, such as 1.2 V. The levels of interconnected lines in the two modes are shown as follows:

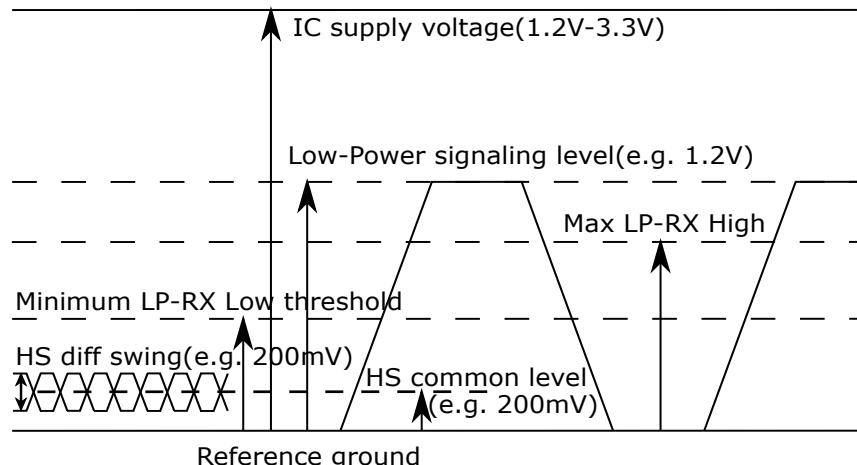

Fig. 12.3: Levels in HS and LP Modes

The two ends of the interconnected line are a driving unit and a receiving unit. The driving unit includes a differential transmitting module (HS_TX) and a low-power single-ended transmitting module (LP_TX), and the receiving unit includes a differential receiving module (HS_RX) and a low-power single-ended receiving module (LP_RX). HS_TX drives the interconnected line with differential signals, and there are two statuses on the high-speed lane: Differential0 and Differential1. LP_TX independently drives two interconnected lines, and there are four statuses on the lane: LP00, LP01, LP10, and LP11. The protocol clearly defines the line levels and configures the HS Mode, Control Mode, and Escape Mode, as shown below:

Lane Pair State Code	Line DC Voltage Levels		High Speed(HS)	Low Power	
	DATA_P	DATA_N	Burst Mode	Control Mode	Escape Mode
HS-0	Low(HS)	High(HS)	Differential-0	Note 1	Note 1
HS-1	High(HS)	Low(HS)	Differential-1	Note 1	Note 1
LP-00	Low(LP)	Low(LP)	Not Defined	Bridge	Space
LP-01	Low(LP)	High(LP)	Not Defined	HS-Request	Mark-0
LP-10	High(LP)	Low(LP)	Not Defined	LP-Request	Mark-1
LP-11	High(LP)	High(LP)	Not Defined	Stop	Note 2

Note:

1. When the lane is in high-speed mode, the low-power receiver (LP_Rx) of each lane will check the LP-00 status code;
2. If the low power receiver (LP-Rx) of each lane recognizes the LP-11 status code, the lane will return to control mode.

Fig. 12.4: Lane Status Code

12.3.3 Clock Lane

The clock lane can be driven to Low Power Mode (LPM), UltraLow Power Mode (ULPM), and High Speed Clock Mode (HSCM). The flow chart of switching between different power modes of the clock lane is as follows:

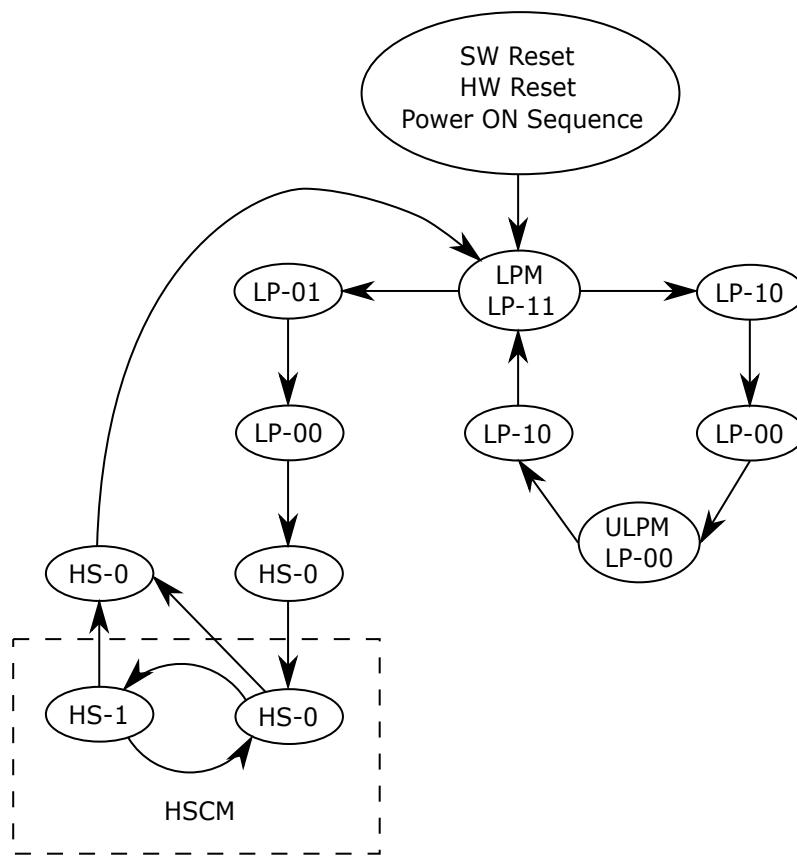

Fig. 12.5: Clock Lane Mode Switching

12.3.3.1 Low Power Mode (LPM, LP11)

Three ways for switching:

1. After the software reset, hardware reset and power-on sequence, the clock lane automatically changes to LP11 (LPM).
2. After leaving LP00 (ULPM), the clock lane changes to LP10 first and then to LP11 (LPM), as shown below:

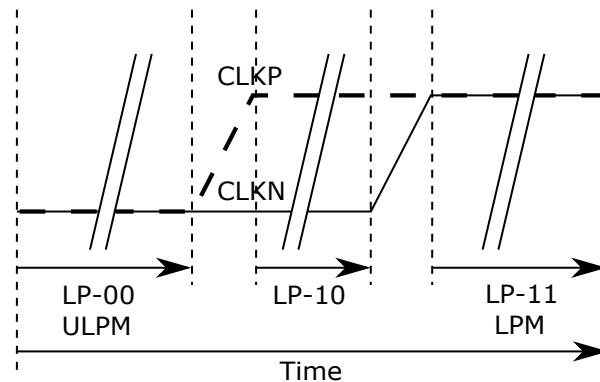

Fig. 12.6: Switching from ULPM to LPM

3. After leaving HS0 or HS1 (HSCM), the clock lane changes to HS0 first and then to LP11 (LPM), as shown below:

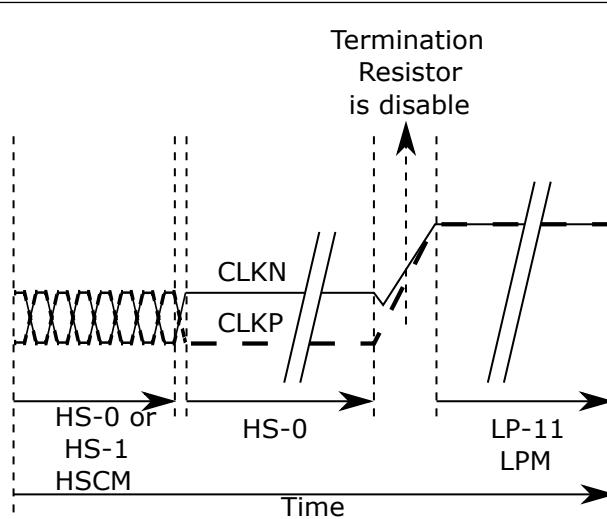

Fig. 12.7: Switching from HSCM to LPM

12.3.3.2 UltraLow Power Mode (ULPM, LP00)

One way for switching: The clock lane switches from LP11 (LPM) to LP10 first and then to LP00 (ULPM), as shown below:

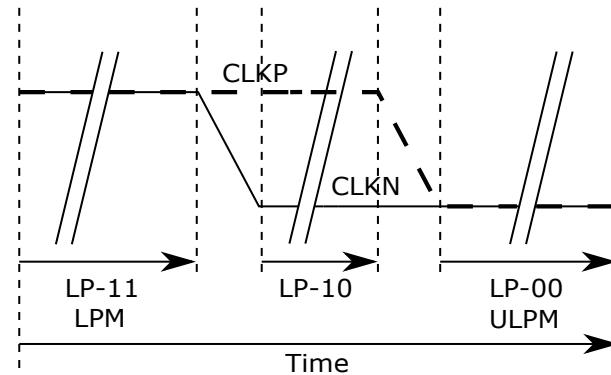

Fig. 12.8: Switching from LPM to ULPM

12.3.3.3 High Speed Clock Mode (HSCM, HS0/1)

One way for switching: The clock lane switches from LP11 (LPM) to LP01, LP00, HS0, and HS0/1 (HSCM) in sequence, as shown below:

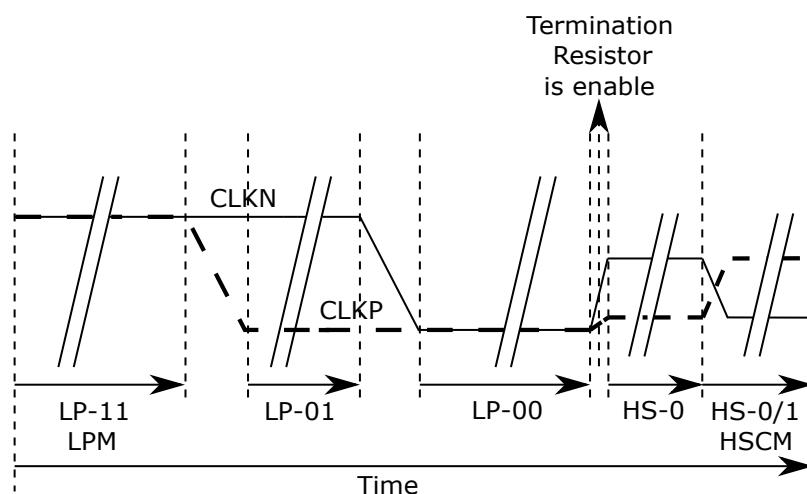

Fig. 12.9: Switching from LPM to HSCM

12.3.4 Data Lanes

All data lanes (D3P/N, D2P/N, D1P/N, and D0P/N) can be driven to HighSpeed Data Transmission (HSDT) Mode, but only data lane 0 (D0P/N) can switch to the Escape Mode and Bus TurnAround Request (BTA) Mode. The entering and leaving sequences of the three modes are shown as follows:

Mode	Entering Mode Sequence	Leaving Mode Sequence
Escape Mode	LP-11 -> LP-10 -> LP-00 -> LP-01 -> LP-00	LP-00 -> LP-10 -> LP-11(Mark-1)
High-Speed Data Transmission	LP-11 -> LP-01 -> LP-00 -> HS-0	(HS-0 or HS-1) -> LP-11
Bus Turnaround Request	LP-11 -> LP-10 -> LP-00 -> LP-10 -> LP-00	Hi-Z

Fig. 12.10: Entering and Leaving Sequences of Three Modes of Data Lanes

12.3.4.1 HighSpeed Data Transmission (HSDT)

When the clock lane of the MCU has switched to the HSCM Mode, the Display Module can switch to the HSDT Mode. The sequence of switching to the HSDT Mode is shown as follows:

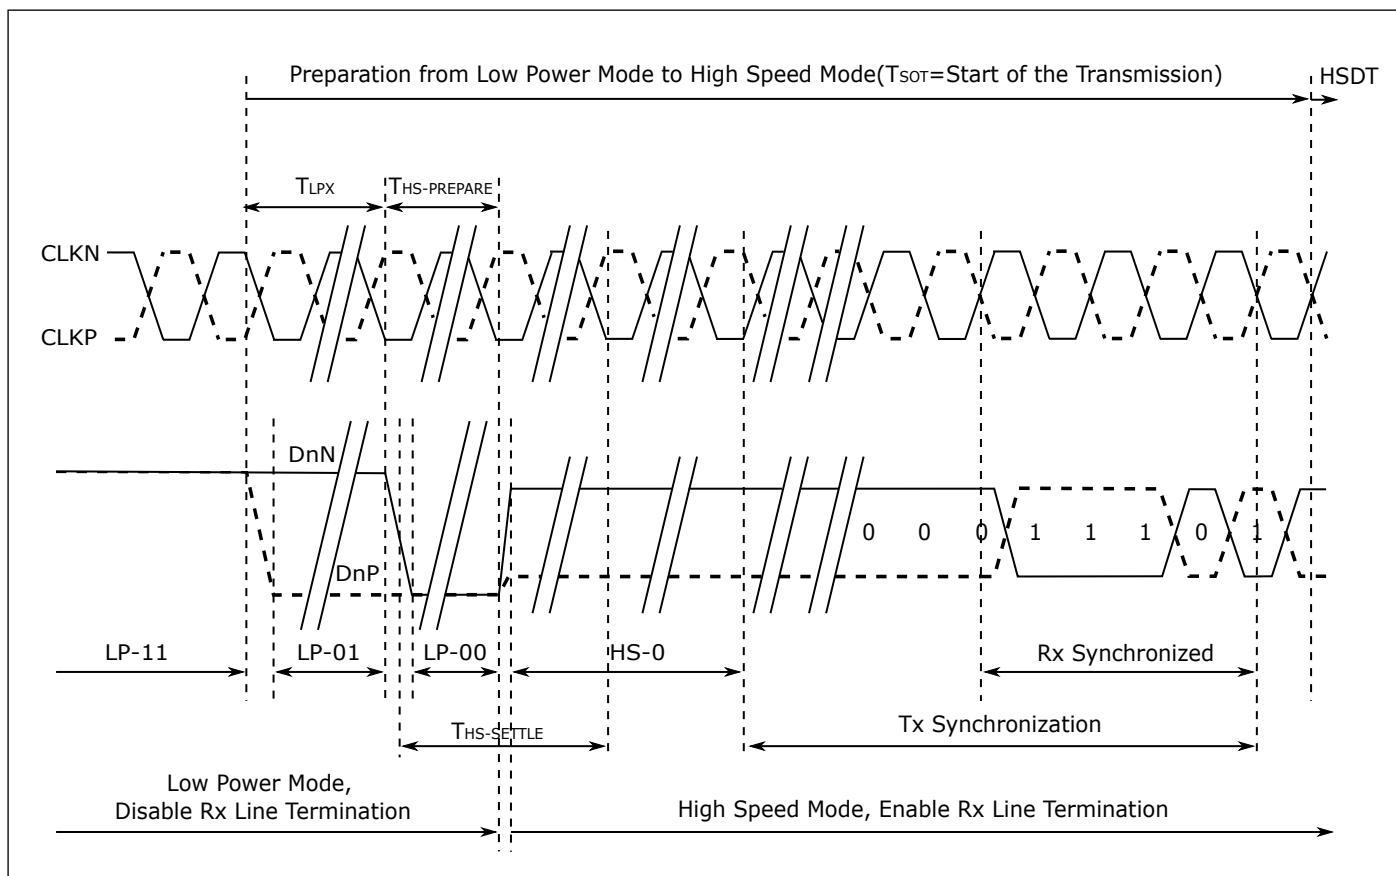

Fig. 12.11: Sequence of Entering HSDT Mode

Sequence:

- Start: LP-11
- HS request: LP01
- HS determination: LP-00=>HS-0 (RX: enabled lane terminal)
- RX synchronization: 011101 (by order of transmitted bits); TX synchronization: 00011101 (by order of transmitted bits)
- End: HSDT, ready to receive loaded high-speed data.

When the clock lane of the MCU is in the HSCM Mode, the Display Module can leave the HSDT Mode, and the clock lane must stay in HSCM until all data lanes switch to the LP11 Mode. The sequence of leaving the HSDT Mode is shown as follows:

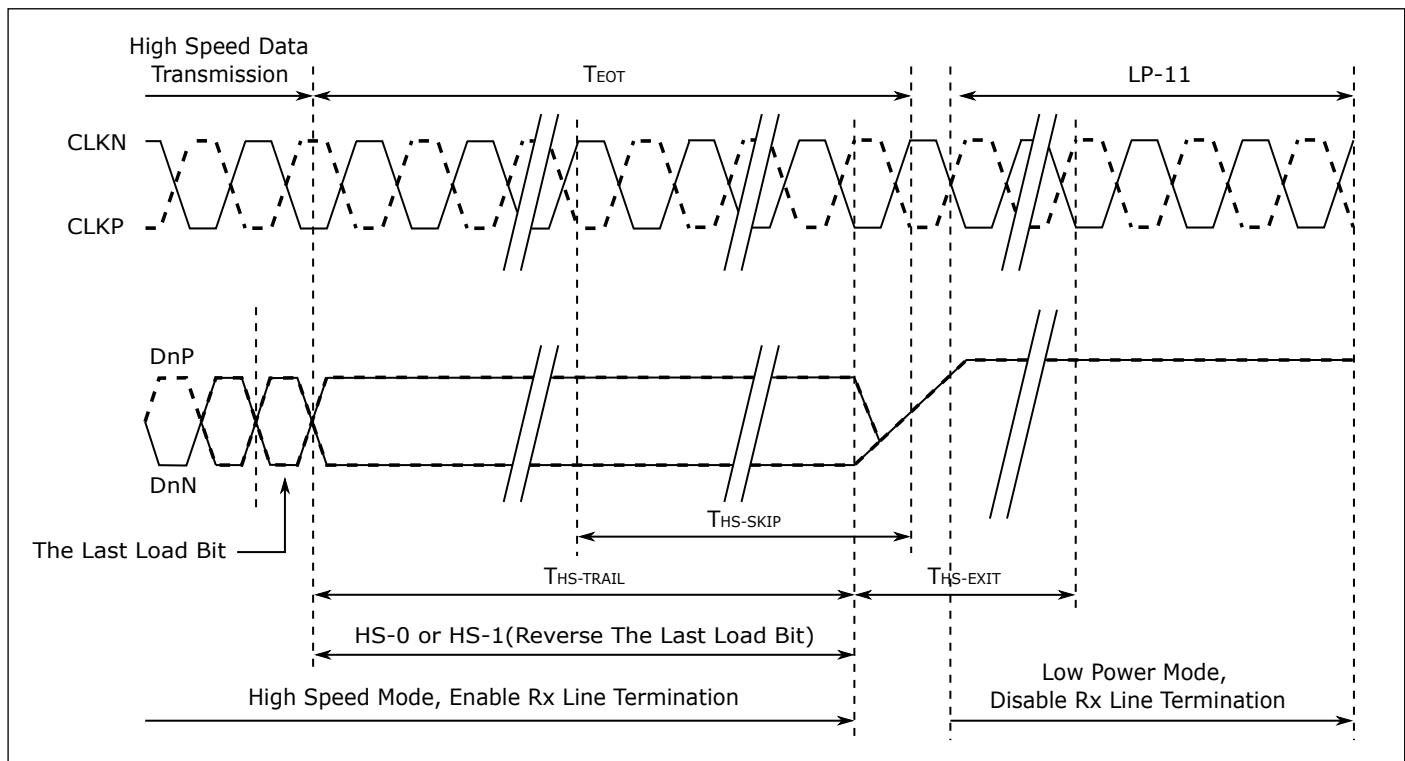

Fig. 12.12: Sequence of Leaving HSDT Mode

Sequence:

- Start: HSDT.
- Stop HSDT: If the last loading bit is HS-0, the MCU changes to HS-1; if the last loading bit is HS-1, MCU changes to HS-0.
- End: LP-11 (RX: disabled lane terminal).

The burst operation of HSDT can be composed of one or multiple packets, which can be either short or long packets.

Here are some different burst examples of HSDT:

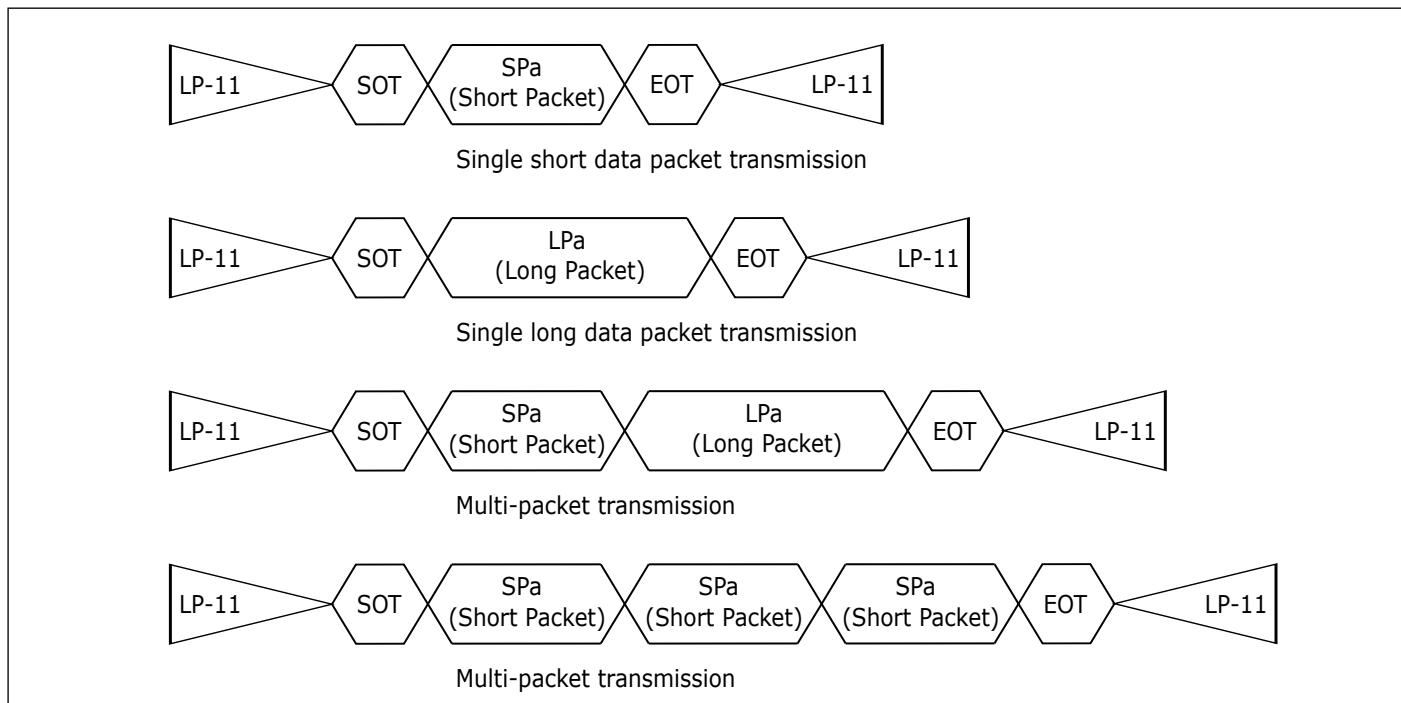

Fig. 12.13: HSDT Burst Sequence

12.3.4.2 Bus Turn-Around(BTA)

When the MCU or Display Module that is controlling the lane D0P/N wants to get information from the RX end, it can initiate a bus turnaround request to reverse the bus control. The MCU and the Display Module initiate the bus turnaround request using the same sequence, as shown below:

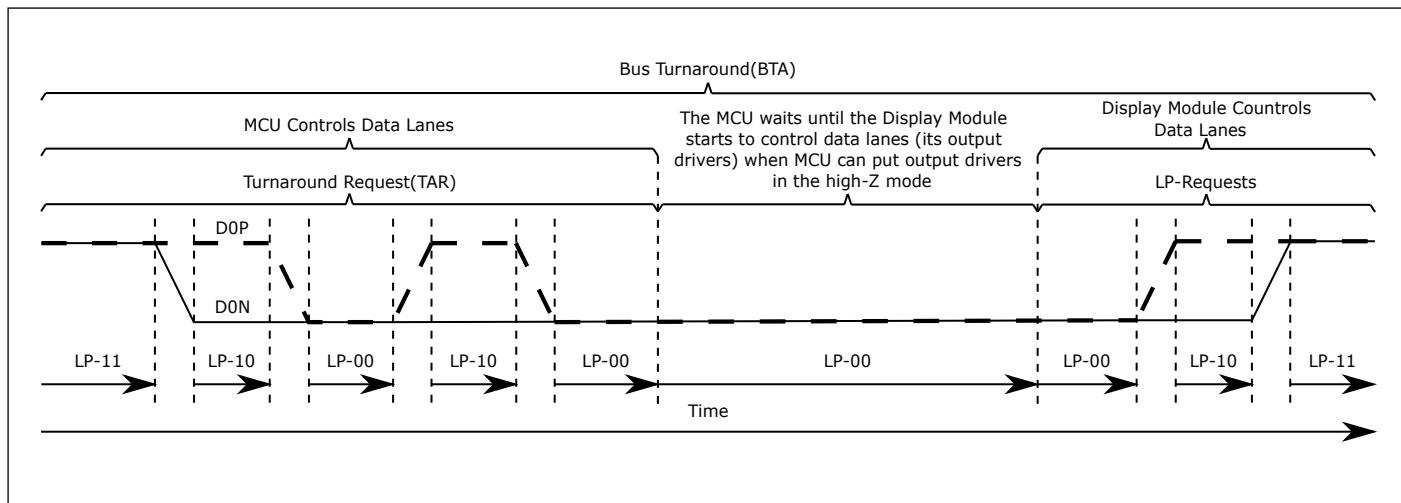

Fig. 12.14: Bus Turnaround Sequence

Sequence:

- Start: LP-11
- Turnaround request (MCU): LP-11=>LP-10=>LP-00=>LP-10=>LP-00
- MCU waits until the Display Module starts to control the lane D0P/N, while the MCU stops controlling the lane D0P/N and sets it to the high-impedance state.
- The Display Module changes to the Stop Mode: LP-00=>LP-10=>LP-11

12.3.4.3 Escape Mode

The Escape Mode, a special mode under LPM, has the following features:

1. Send LPDT command from the MCU to the Display Module.
2. Drive data lanes to the ULPS state.
3. Send a RAR command to reset the Display Module.
4. Send an ACK signal for transmitting non-error events from the Display Module to the MCU.

The basic sequence of the Escape Mode is shown as follows:

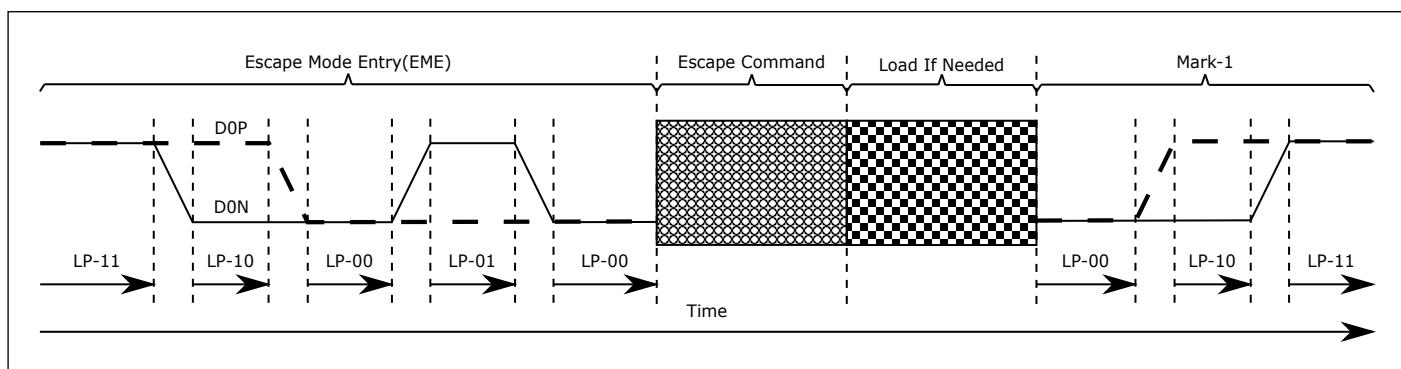

Fig. 12.15: Escape Mode Sequence

Sequence:

- Start: LP-11
- Switch to the Escape Mode (EME): LP-11=>LP-10=>LP-00=>LP-01=>LP-00
- Escape command (EC): When one of the data lanes changes from Low to High and then goes Low, this change shows the value of the current data bit ($D0P = 1, D0N = 0$)
- When the data lane 0 changes from Low to High and then goes Low, the receiver latches 1 bit data, that is, logic 0. The receiver takes the transmission from Low to High and then to Low
- as its internal clock

- If necessary, load the data
- Leave the Escape Mode: LP-00=>LP-10=>LP-11
- End: LP-11

Escape command types are shown in the following table:

Escape Command	Command Type	Entry Command Pattern (First Bit->Last Bit Transmitted)	Dn	D0
Low-Power Data Transmission	Mode	1110 0001 b	✗	✓
Ultra-Low Power Mode	Mode	0001 1110 b	✓	✓
Note 1	Mode	1001 1111 b	✗	✗
Note 1	Mode	1101 1110 b	✗	✗
Remote Application Reset	Trigger	0110 0010 b	✗	✓
Tearing Effect	Trigger	0101 1101 b	✗	✗
Acknowledge	Trigger	0010 0001 b	✗	✓
Note 1	Trigger	1010 0000 b	✗	✗

Note:

1. The support of this command has not been implemented on the display module;
2. The value of n is 1, 2 and 3;
3. "✓" means support;
4. "✗" means not supported.

Fig. 12.16: Escape Commands

12.3.4.4 Low Power Data Transmission (LPDT)

When the data lane changes to the Escape Mode and the MCU has sent the LPDT command to the Display Module, the MCU can send the data to the Display Module in the LPM. The Display Module also uses the same sequence when sending data to the MCU. The LPDT sequence is shown as follows:

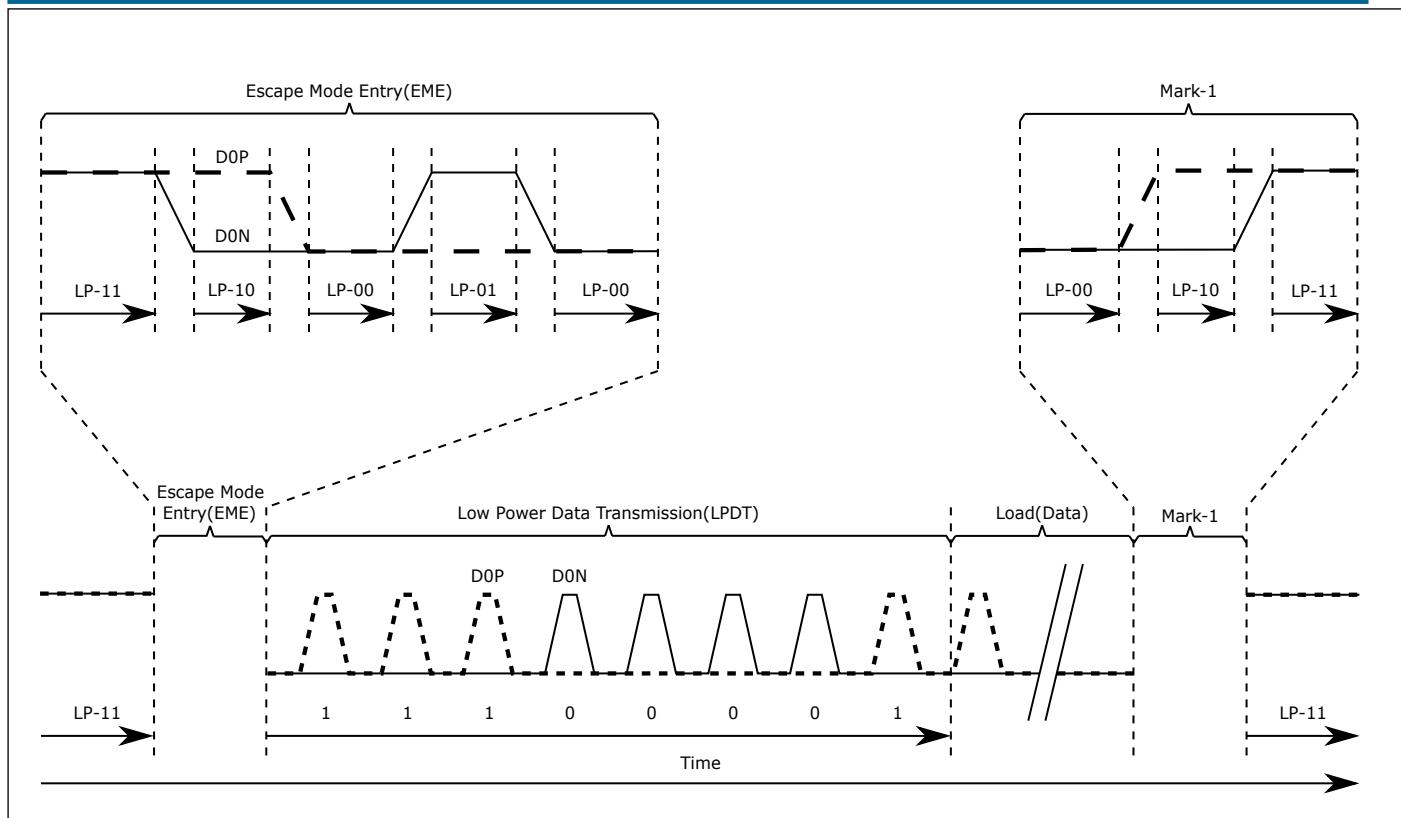

Fig. 12.17: LPDT Sequence

Sequence:

- Start: LP-11
- Switch to the Escape Mode (EME): LP-11=>LP-10=>LP-00=>LP-01=>LP-00
- Send the LPDT command in the Escape Mode: 0x87 (LSBfirst).
- Data loading: One or more bytes, which are in a suspended state when the data lane stops between bytes (all lanes are Low).
- Leave the Escape Mode: LP-00=>LP-10=>LP-11
- End: LP-11

12.3.4.5 UltraLow Power State (ULPS)

When the data lane switches to the Escape Mode, MCU can mandatorily change the data lane to the ULPS. The ULPS sequence is shown as follows:

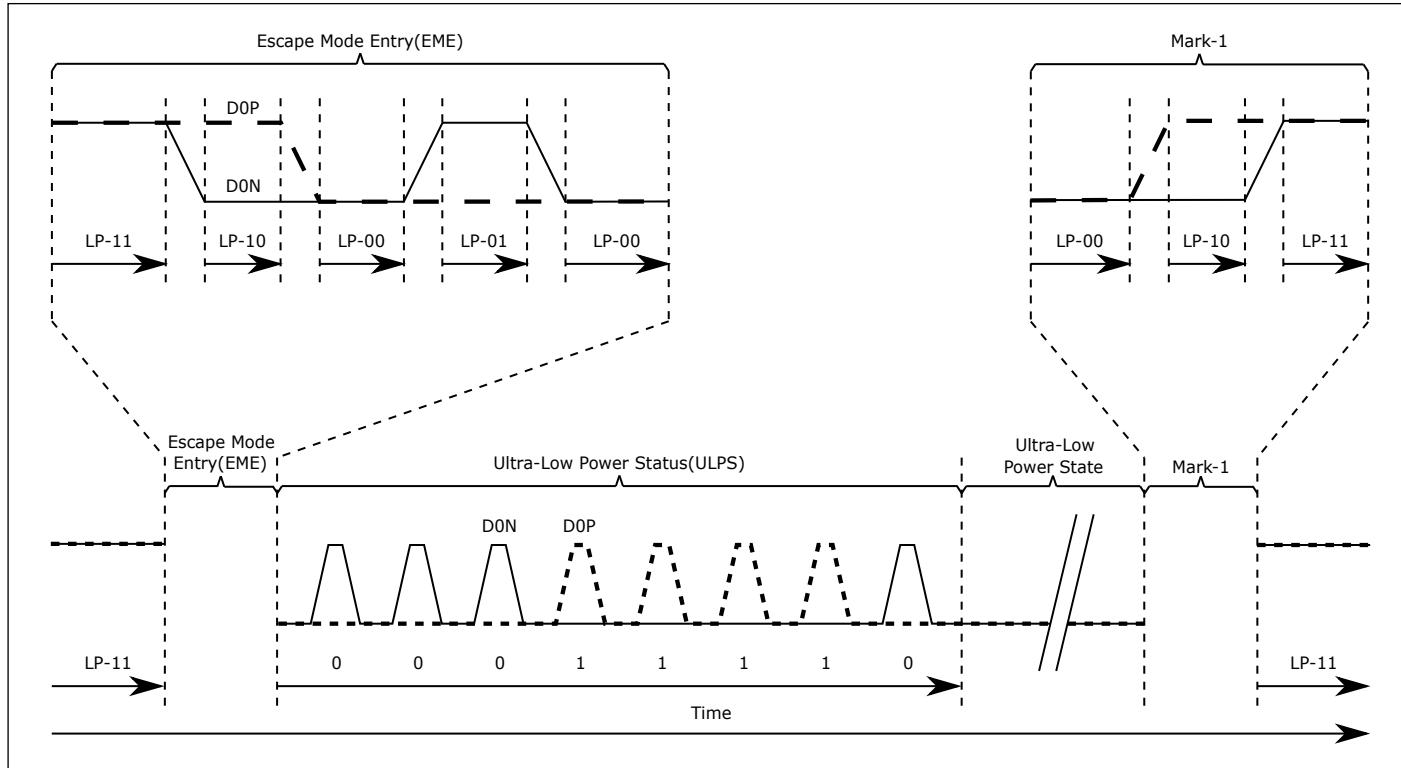

Fig. 12.18: ULPS Sequence

Sequence:

- Start: LP-11
- Switch to the Escape Mode (EME): LP-11=>LP-10=>LP-00=>LP-01=>LP-00
- Send the ULPS command in the Escape Mode: 0x78 (LSBfirst)
- ULPS: The MCU keeps the data lane Low
- Leave the Escape Mode: LP-00=>LP-10=>LP-11
- End: LP-11(after the data lane exits ULPS, wait 100 us before sending the next command)

12.3.4.6 Remote Application Reset (RAR)

RAR is one of the Trigger commands. When the data lane switches to the Escape Mode, the MCU can inform the Display Module to reset in the remote application reset trigger. The RAR sequence is shown as follows:

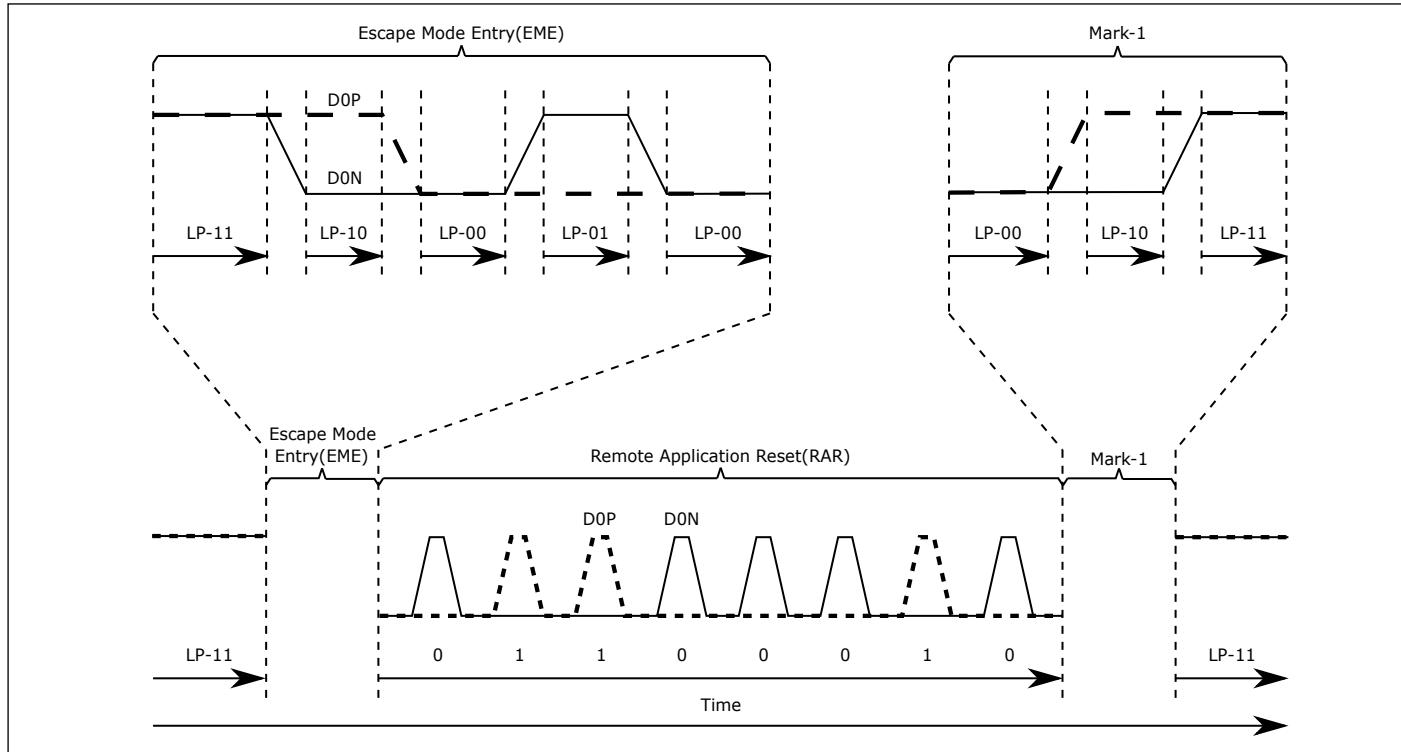

Fig. 12.19: RAR Sequence

Sequence:

- Start: LP-11
- Switch to the Escape Mode (EME): LP-11=>LP-10=>LP-00=>LP-01=>LP-00
- Send the RAR command in the Escape Mode: 0x46 (LSBfirst)
- Leave the Escape Mode: LP-00=>LP-10=>LP-11
- End: LP-11

12.3.4.7 Acknowledgement (ACK)

ACK is one of the Trigger commands. The Display Module can notify the MCU of unrecognized errors through ACK. The Display Module sends ACK in a sequence shown in the following figure:

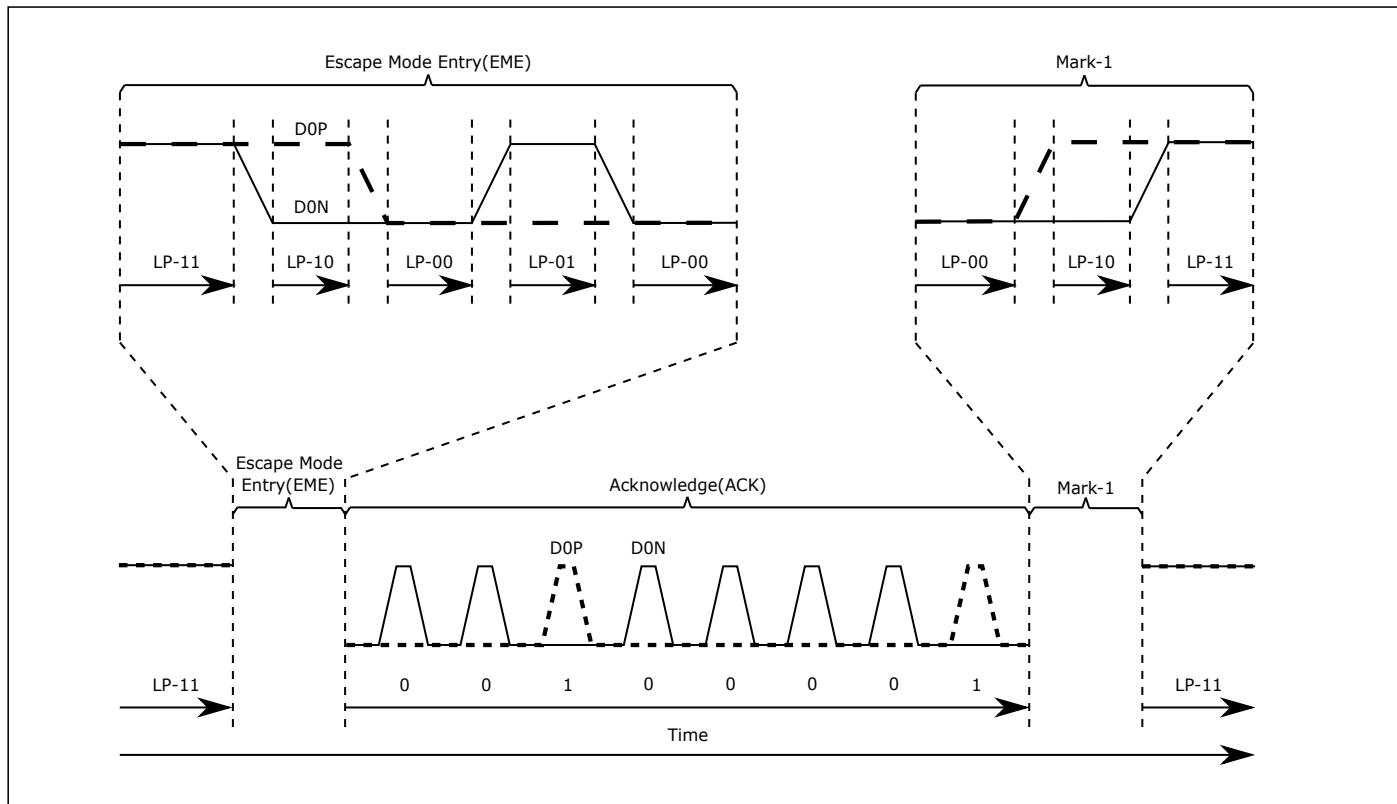

Fig. 12.20: ACK Sequence

Sequence:

- Start: LP-11
- Switch to the Escape Mode (EME): LP-11=>LP-10=>LP-00=>LP-01=>LP-00
- Send the ACK command in the Escape Mode: 0x84 (LSBfirst)
- Leave the Escape Mode: LP-00=>LP-10=>LP-11
- End: LP-11

12.3.5 Lane Management Layer

The lanes of DSI are expandable. The number of data lanes can be one, two, three, or four as expanded based on the bandwidth requirements of practical applications, and the peak bus bandwidth can gain an approximate linear increase. At the TX end, this layer aims to distribute the data from the protocol layer to each data lane in a certain order. At the RX end, this layer aims to collect transmitted bytes from each lane and merge them into a complete packet. All data lanes share a clock signal, but data transfer on each lane may not be completed simultaneously. When the number of bytes transmitted is not an integral multiple of the number of lanes, some lanes will finish data transfer before others. Except for Lane0, the order of the other three lanes can be configured by <CR_LANE_MUX_SEL>.

There are four orders:

- Lane0, Lane1, Lane2, Lane3
- Lane0, Lane3, Lane1, Lane2
- Lane0, Lane2, Lane3, Lane1
- Lane0, Lane2, Lane1, Lane3

Taking the single lane and four lanes (Lane0, Lane1, Lane2, Lane3) as examples, the TX end is shown as follows:

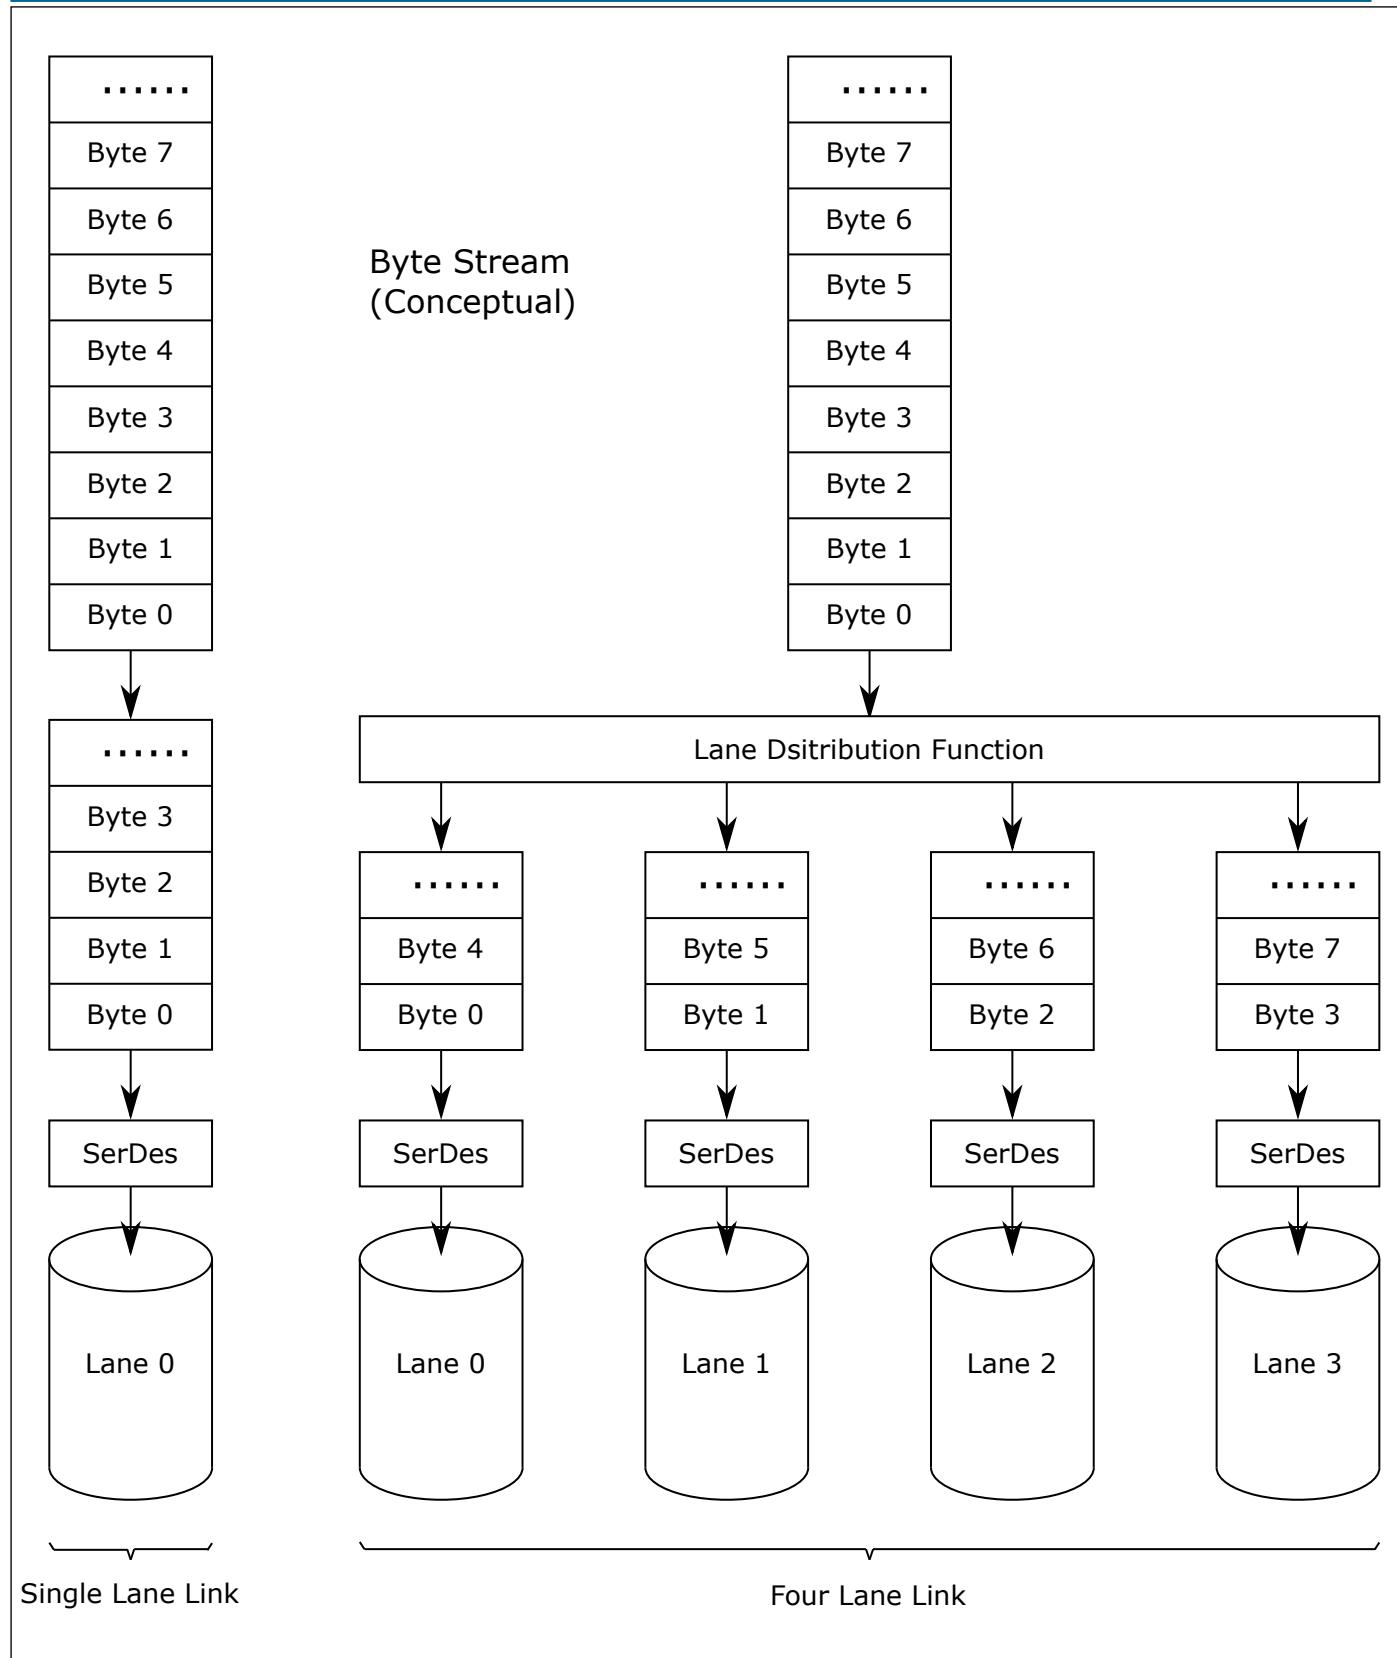

Fig. 12.21: TX End Distribution

The RX end is shown as follows:

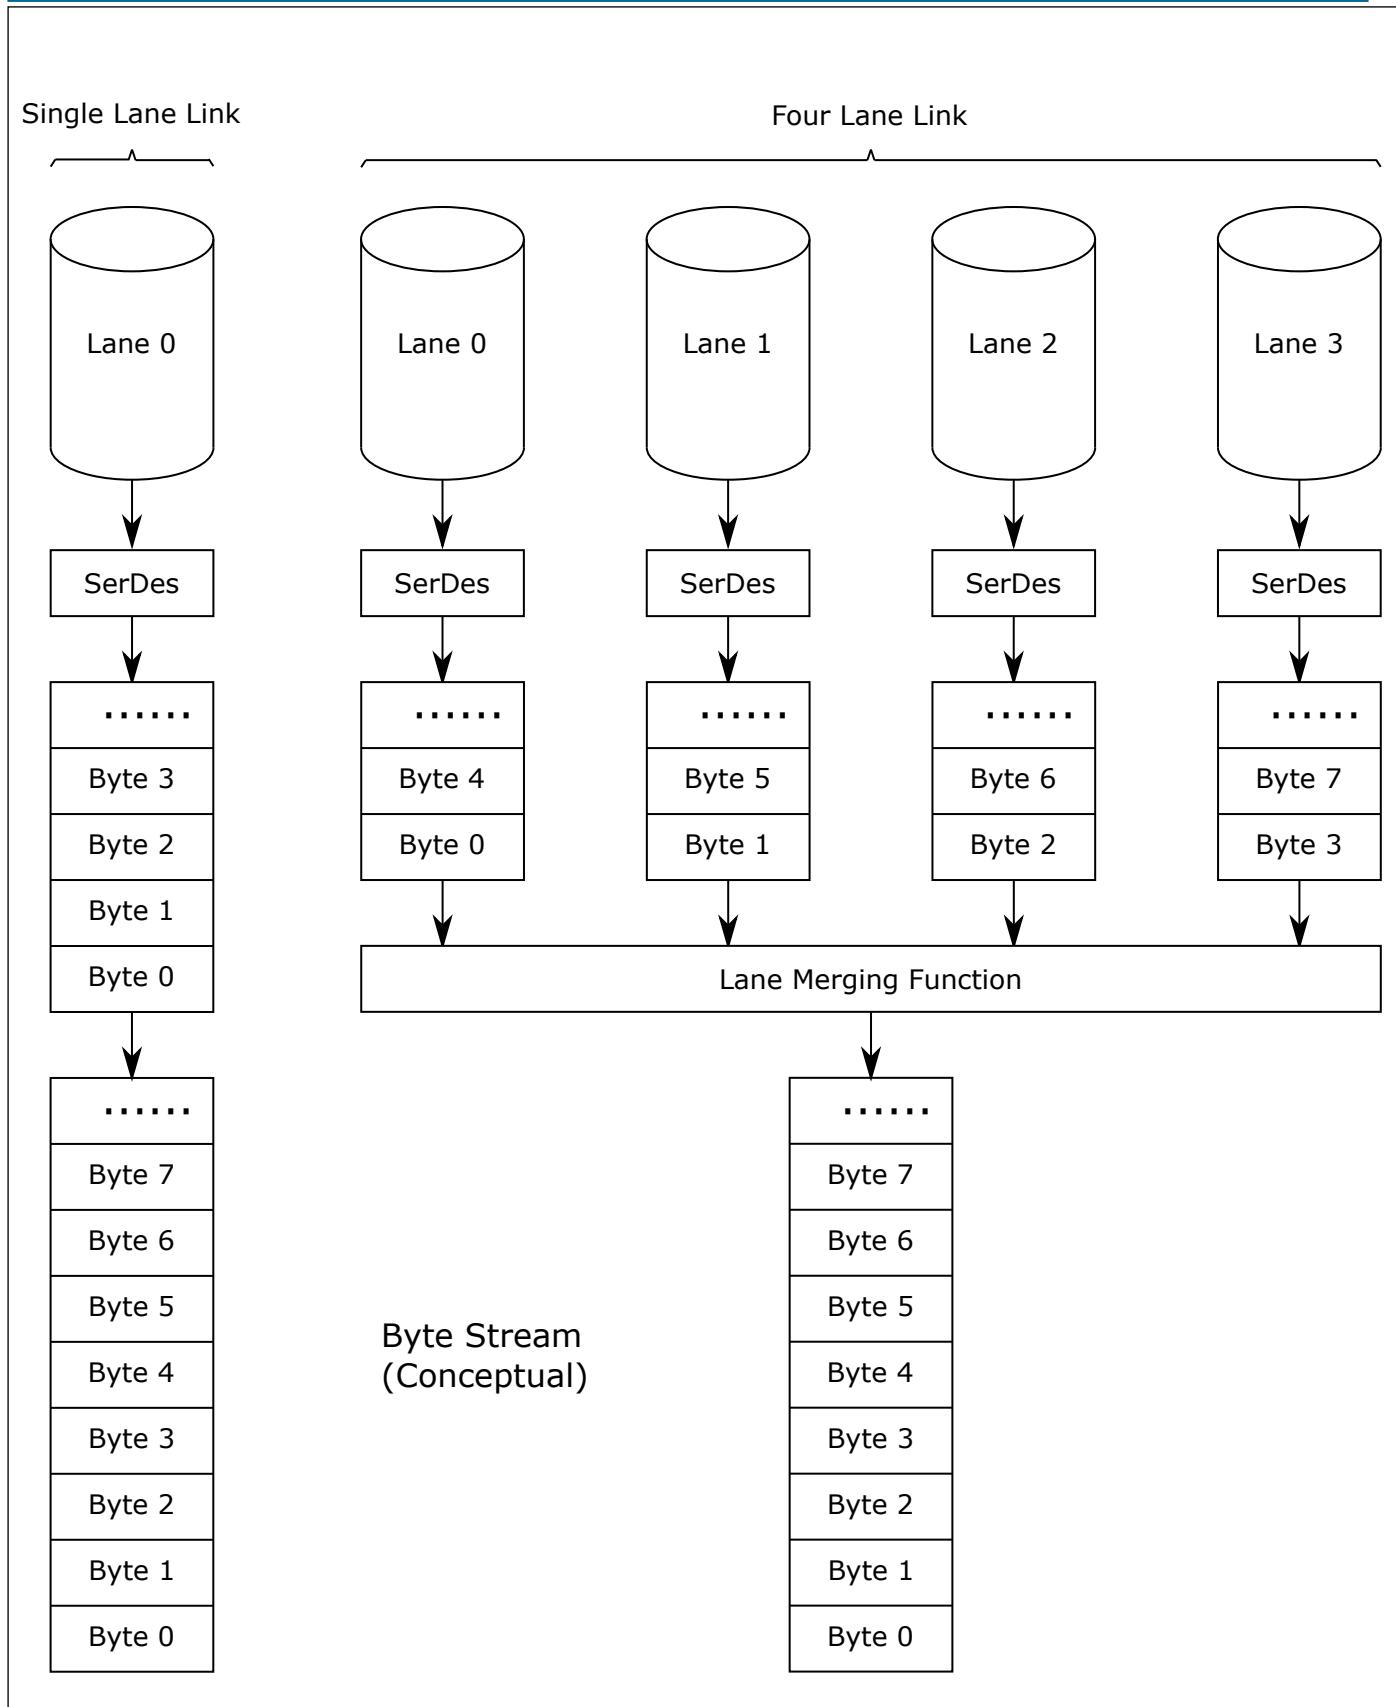

Fig. 12.22: RX End Merging

The lane distributor accepts HS transmission with arbitrary byte length, buffers N bytes, where N is the number of lanes implemented in the interface, and sends N byte arrays on N lanes in parallel. Before sending data, all lanes execute the SoT sequence in parallel to indicate the start of the first byte of the packet to the corresponding receiving unit. After the SoT, the lane sends N byte arrays from the first packet in parallel through a cyclic process. For a four-lane system, Byte 0 of the packet enters Lane 0, Byte 1 enters Lane 1, Byte 2 enters Lane 2, Byte 3 enters Lane 3, Byte 4 enters Lane 0, and so on. As HS transmission involves any number of bytes, which may not be an integral multiple of the number of lanes, some lanes will finish data transfer before others. Although all lanes start transmission at the same time by executing SoT in parallel, each lane runs independently and some lanes may complete HS transmission before others and send EoT one byte in advance. It is as shown below:

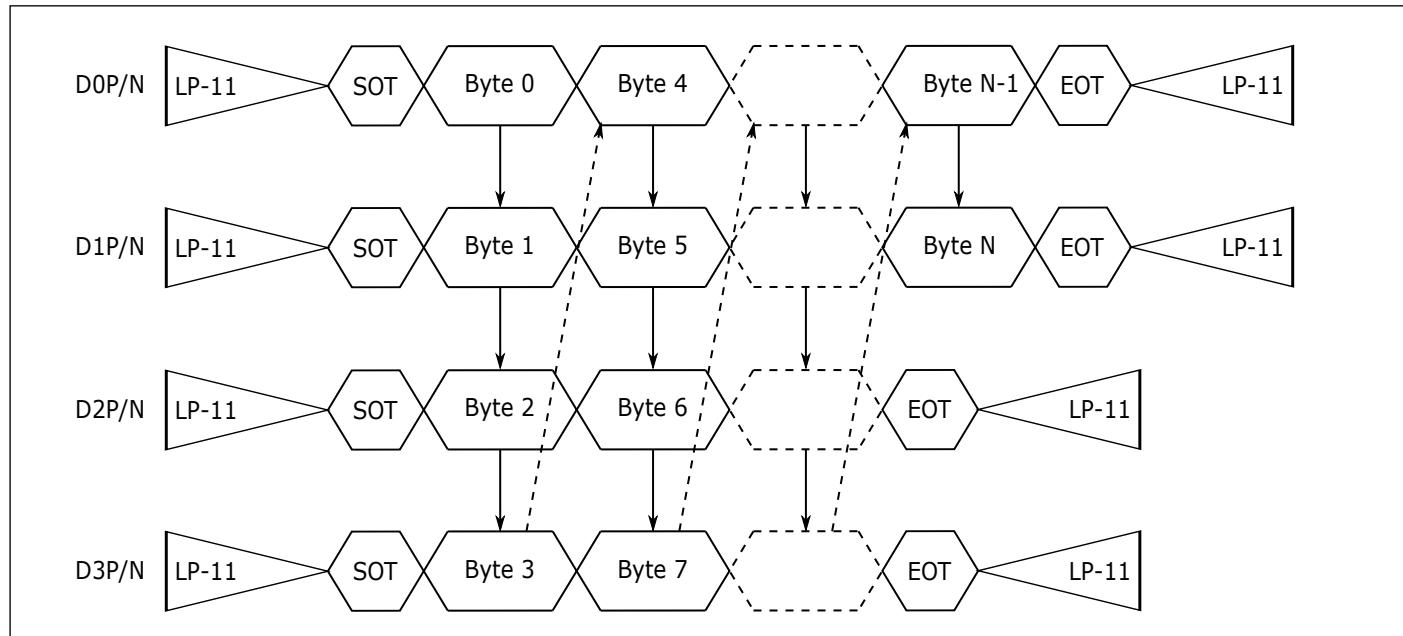

Fig. 12.23: Transmission of Bytes (Non-integral Multiple of the Number of Lanes)

12.3.6 Protocol Layer

DSI is a communication protocol based on packet transmission. Essentially, the commands and data are transmitted between the MCU and the Display Module in the packet format. DSI defines short packet (SPa) and long packet (LPa). The type of packet (SPa or LPa) can be identified from its header (PH).

12.3.6.1 Short Packet

A short packet consists of 8-bit data identification (DI), two bytes of commands or data, and 8-bit ECC. The length of a short packet is 4 bytes including ECC. Short packets are mainly used for most command pattern commands and related parameters and also used to transmit events like H-sync and V-sync edges. Due to short length, the timing information can be accurately transmitted to the peripheral logic. The structure of a short packet is shown as follows:

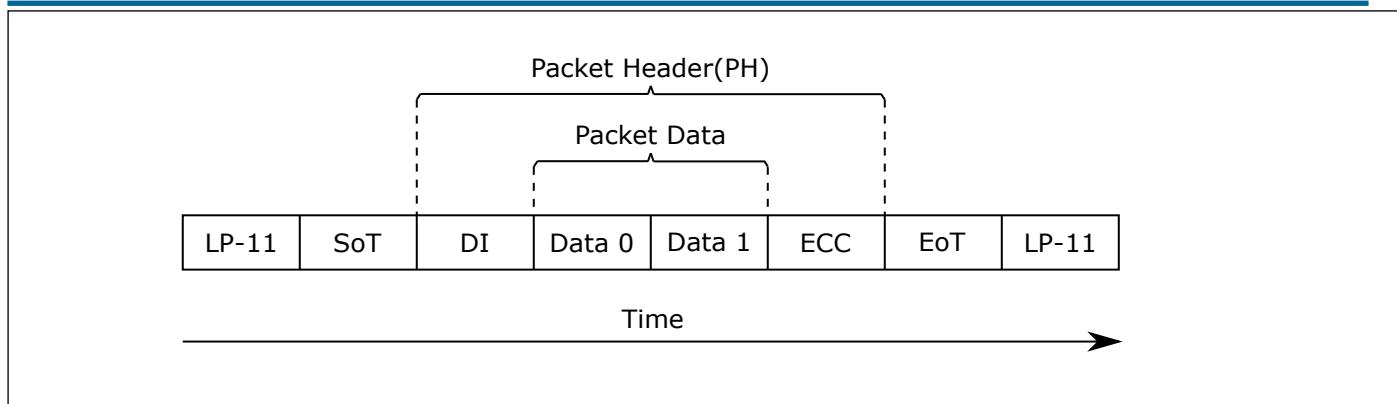

Fig. 12.24: Structure of Short Packet

- LP-11: low power stop state
- SoT: start of transmission
- DI: 8-bit, data identification
- Data 0: 8-bit, packet data 0
- Data 1: 8-bit, packet data 1
- ECC: 8-bit, error correction code
- EoT: end of transmission

12.3.6.2 Long Packet

The long packet consists of a 32-bit packet header (PH), a data payload with a variable number of bytes, and a 16-bit packet footer (PF). The packet header consists of 8-bit data identification, 16-bit word count (WC), and 8-bit ECC. Since the WC that records the payload length is two bytes, and the value ranges from 0 to 65,535, the length of a long packet ranges from 6 to 65,541 bytes. Long packets are mainly used to transmit a large amount of image data or some control commands. The structure of a long packet is shown as follows:

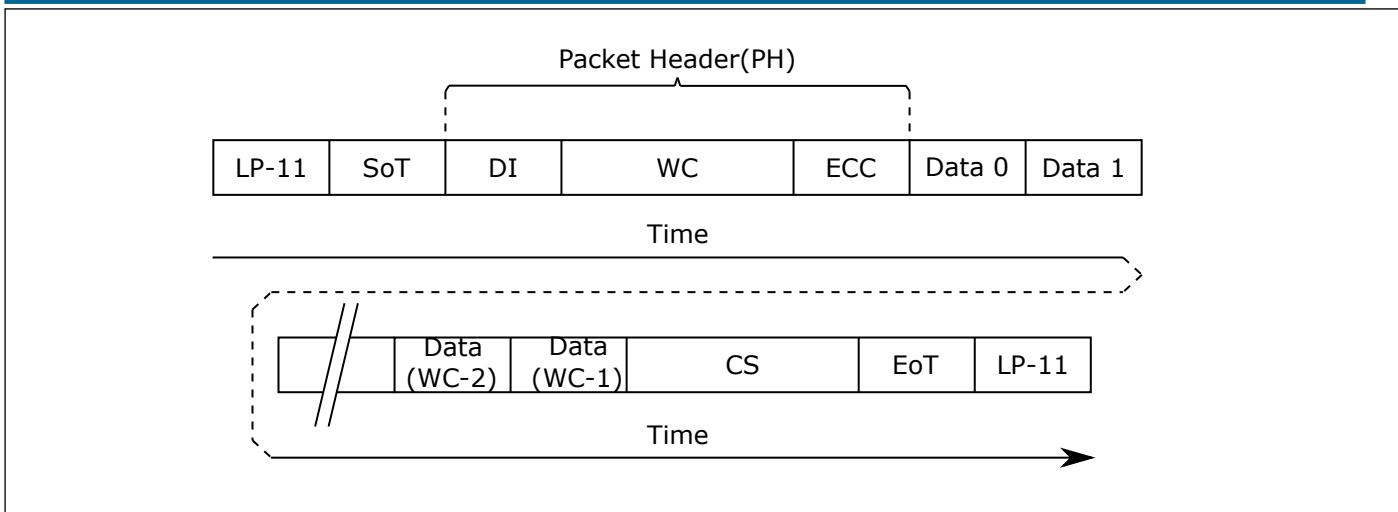

Fig. 12.25: Structure of Long Packet

- LP-11: low power stop state
- SoT: start of transmission
- DI: 8-bit, data identification
- WC: 16-bit, word count
- ECC: 8-bit, error correction code
- Data 0, Data 1…: packet data (0–65535 bytes)
- CS: 16-bit, checksum
- EoT: end of transmission

12.3.6.3 Multiple Packets per Transmission

In the above structural diagrams of short and long packets, the transmission contains only one packet. For multiple packets, if only one packet is sent in each transmission, the overhead of frequent switching between LPS and HS Mode will greatly limit the bandwidth. DSI allows multiple packets to be concatenated and sent without SoT, EoT and LP11 between packets, as shown below:

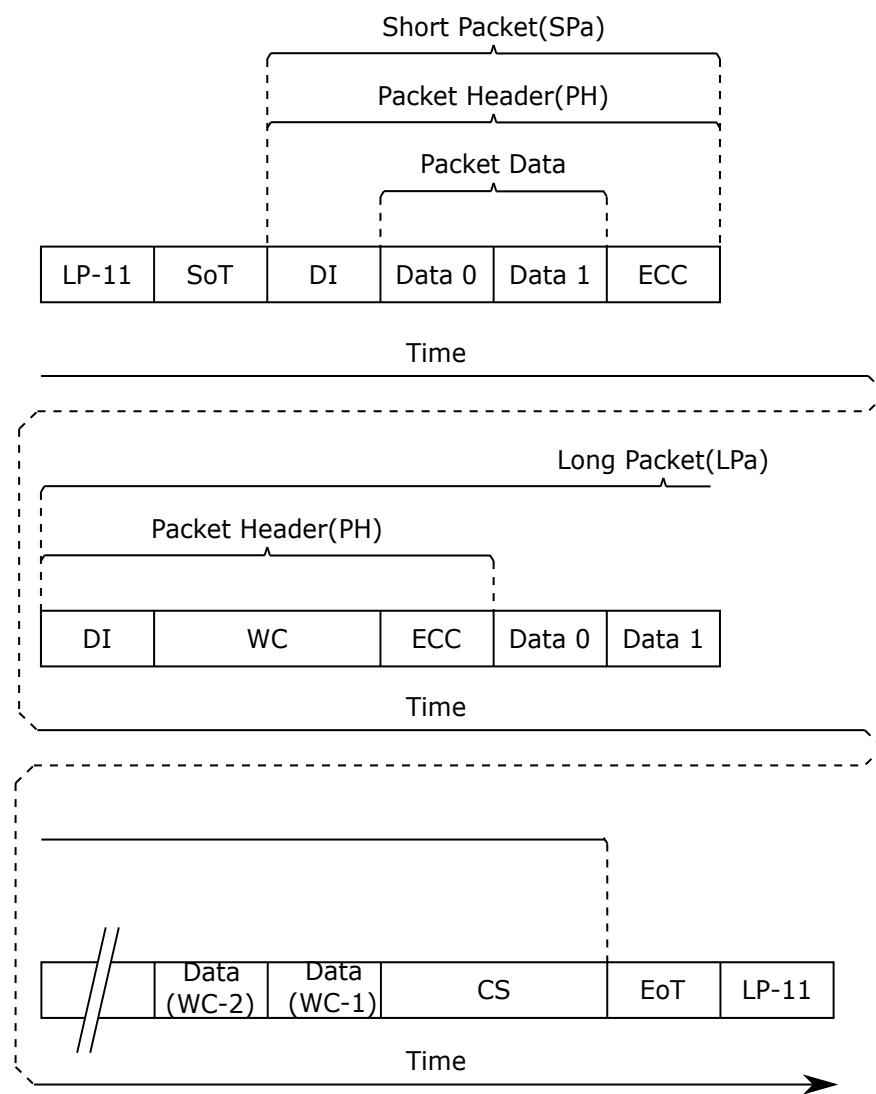

Fig. 12.26: Multiple Packets per Transmission

12.3.6.4 Bit Order of Bytes in a Packet

The bit order of the bytes used in a packet is that the LSB is sent first and the MSB is sent last. The following figure shows an example:

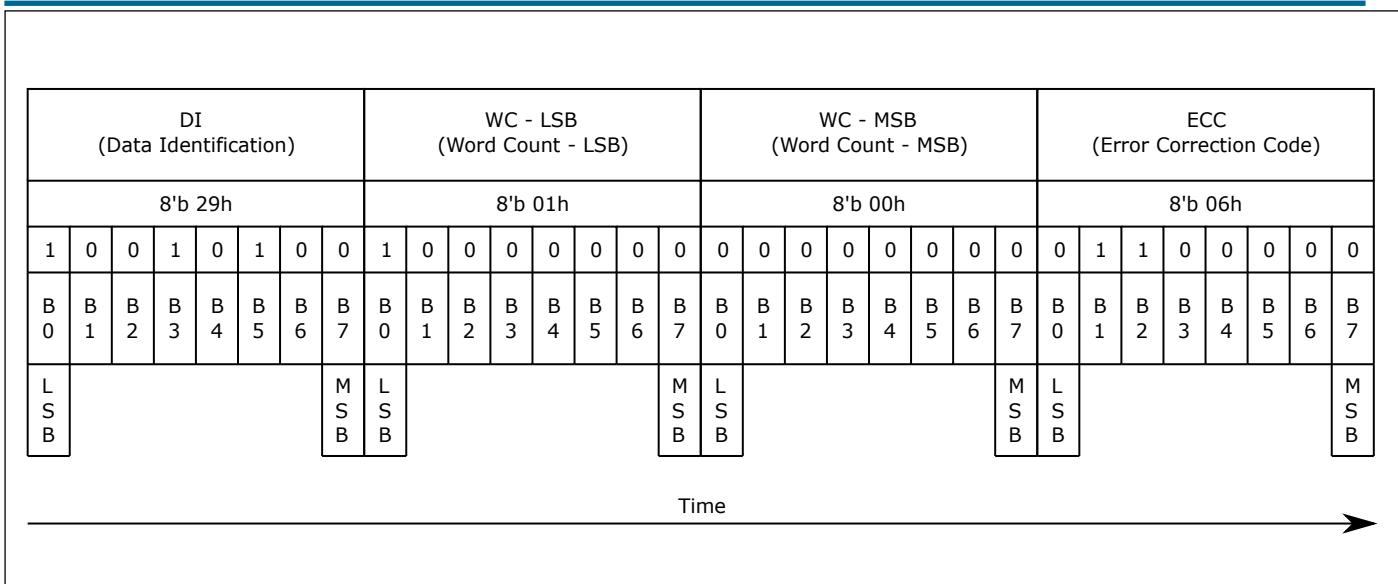

Fig. 12.27: Bit Order of Bytes in a Packet

12.3.6.5 Byte Order in a Packet

The byte order of multi-byte information used in a packet is that the LSB is sent first and the MSB is sent last. For example, the word count (WC) consists of 2 bytes. LSB is sent before the MSB, as shown below:

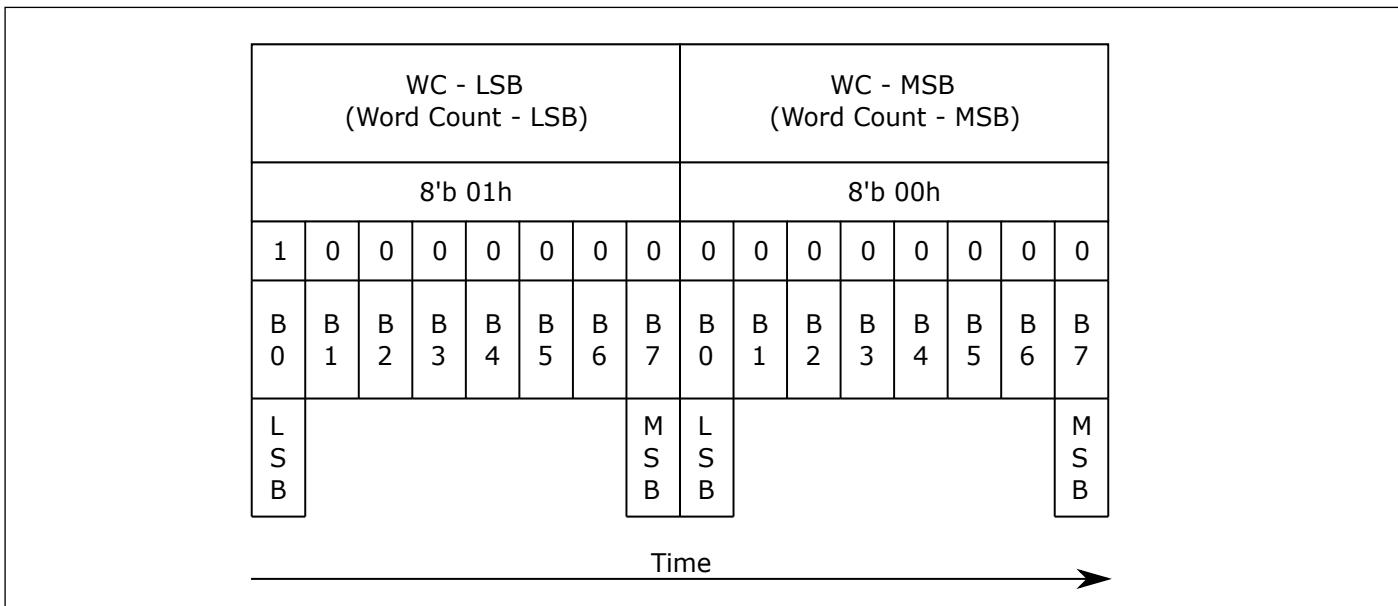

Fig. 12.28: Byte Order in a Packet

12.3.6.6 Packet Header (PH)

The packet header always consists of 4 bytes, and the contents of the 4 bytes are different for short and long packets. The short packet consists of 1-byte data identification (DI), 2-byte packet data (PD0, PD1), and 1-byte ECC. The long packet consists of 1-byte data identification (DI), 2-byte word count (WC), and 1-byte ECC.

12.3.6.7 Data Identification (DI)

DI, a part of the PH, consists of two parts:

- Virtual channel (VC), 2-bit, DI[7:6]
- Data type (DT), 6-bit, DI[5:0]

12.3.6.8 Virtual Channel (VC)

VC, a part of data identification (DI[7:6]) structure, is used to determine the destination to which MCU packets are sent. The virtual channel can allocate 4 different lanes to 4 different Display Modules, and each module uses the same virtual channel used by the MCU to send packets to it.

12.3.6.9 Data Type (DT)

DT, a part of data identification (DI[5:0]) structure, is used to define a short or long packet type and the packet format. The data types from the MCU to the Display Module are defined in the following table:

From the MCU to the Display Module								
Bit5	Bit4	Bit3	Bit2	Bit1	Bit0	Hex	Description	Short/Long Packet
0	0	0	0	0	1	01	Sync Event, V Sync Start	SPa (Short Packet)
0	1	0	0	0	1	11	Sync Event, V Sync End	SPa (Short Packet)
1	0	0	0	0	1	21	Sync Event, H Sync Start	SPa (Short Packet)
1	1	0	0	0	1	31	Sync Event, H Sync End	SPa (Short Packet)
0	0	1	0	0	0	08	End of Transmission Packet (EoTP), Note 1	SPa (Short Packet)
0	0	0	0	1	0	02	Color Mode Off Command	SPa (Short Packet)
0	1	0	0	1	0	12	Color Mode On Command	SPa (Short Packet)
1	0	0	0	1	0	22	Shut Down Peripheral Command	SPa (Short Packet)
1	1	0	0	1	0	32	Turn On Peripheral Command	SPa (Short Packet)
0	0	0	0	1	1	03	Generic Short Write, No Parameter	SPa (Short Packet)
0	1	0	0	1	1	13	Generic Short Write, 1 Parameter	SPa (Short Packet)
1	0	0	0	1	1	23	Generic Short Write, 2 Parameters	SPa (Short Packet)
0	0	0	1	0	0	04	Generic Short Read, No Parameter	SPa (Short Packet)
0	1	0	1	0	0	14	Generic Short Read, 1 Parameter	SPa (Short Packet)
1	0	0	1	0	0	24	Generic Short Read, 2 Parameters	SPa (Short Packet)
0	0	0	1	0	1	05	DCS Write, No Parameter	SPa (Short Packet)
0	1	0	1	0	1	15	DCS Write, 1 Parameter	SPa (Short Packet)
0	0	0	1	1	0	06	DCS Read, No Parameter	SPa (Short Packet)
1	1	0	1	1	1	37	Set Maximum Return Packet Size	SPa (Short Packet)
0	0	1	0	0	1	09	Null Packet, No Data, Note 2	LPa (Long Packet)
0	1	1	0	0	1	19	Blanking Packet, No Data	LPa (Long Packet)
1	0	1	0	0	1	29	Generic Long Write	LPa (Long Packet)
1	1	1	0	0	1	39	DCS Write Long	LPa (Long Packet)
0	0	1	1	1	0	0E	Packed Pixel Stream, 16-bit RGB, 5-6-5 Format	LPa (Long Packet)
0	1	1	1	1	0	1E	Packed Pixel Stream, 18-bit RGB, 6-6-6 Format	LPa (Long Packet)
1	0	1	1	1	0	2E	Loosely Packed Pixel Stream, 18-bit RGB, 6-6-6 Format	LPa (Long Packet)
1	1	1	1	1	1	3E	Packed Pixel Stream, 24-bit RGB, 8-8-8 Format	LPa (Long Packet)
x	x	0	0	0	0	x0	Do Not Use	
x	x	1	1	1	1	xF	All Unspecified Codes Are Reserved	

Note:

1. This item can be used when the MCU wants to confirm the end of the transmission in the high-speed data transmission mode;
2. This item can be used when the data channel remains in high-speed data transfer mode.

Fig. 12.29: Data Types from the MCU to the Display Module

The data types from the Display Module to the MCU are defined in the following table:

From the Display Module to the MCU								
Bit5	Bit4	Bit3	Bit2	Bit1	Bit0	Hex	Description	Short/Long Packet
0	0	0	0	1	0	02	Acknowledge with Error Report	SPa (Short Packet)
0	0	1	0	0	0	08	End of Transmission Packet (EoTP)	SPa (Short Packet)
0	1	0	0	0	1	11	Generic Short Read Response, 1 Byte Returned	SPa (Short Packet)
0	1	0	0	1	0	12	Generic Short Read Response, 2 Bytes Returned	SPa (Short Packet)
0	1	1	0	1	0	1A	Generic Long Read Response	LPa (Long Packet)
0	1	1	1	0	0	1C	DCS Read Long Response	LPa (Long Packet)
1	0	0	0	0	1	21	DCS Read Short Response, 1 Byte Returned	SPa (Short Packet)
1	0	0	0	1	0	22	DCS Read Short Response, 2 Bytes Returned	SPa (Short Packet)

Fig. 12.30: Data Types from the Display Module to the MCU

12.3.6.10 Packet Data (PD)

For short packets, PD is a part of the PH, located after the data identification, and is fixed to 2 bytes, namely data 0 and data 1. The order of sending PD is sending data 0 before data 1. If the length of information is 1 byte, the value of data 1 is 0. For long packets, PD is located after the PH, and the byte length depends on the WC.

12.3.6.11 Word Count (WC)

WC is a part of the header of a long packet and located after the data identification. It is used to determine the total number of bytes in the PD of a long packet. WC is fixed to 2 bytes. The LSB is sent before the MSB.

12.3.6.12 Error Correction Code (ECC)

ECC, a part of the PH, can identify one or more errors and correct only one error. ECC protects the following fields:

- short packet: DI (8-bit), PD (16-bit) and ECC (8-bit)
- long packet: DI (8-bit), WC (16-bit) and ECC (8-bit)

Taking short packets as an example, the ECC calculation method for each byte is shown as follows (" ^ " indicates exclusive OR operation).

DI (Data Identification)								Data 0 (Packet Data)								Data 1 (Packet Data)								ECC (Error Correction Code)									
8'b 05h								8'b 10h								8'b 00h								8'b 2Ch									
1	0	1	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	0	1	0	0

12.3.6.13 Packet Footer (PF)

PF, a part of a long packet, is located after the packet data. PF is a checksum calculated from the packet data of a long packet. The checksum is a 16-bit cyclic redundancy check (CRC) value generated by the polynomial $X^{16}+X^{12}+X^5+X^0$, as shown below:

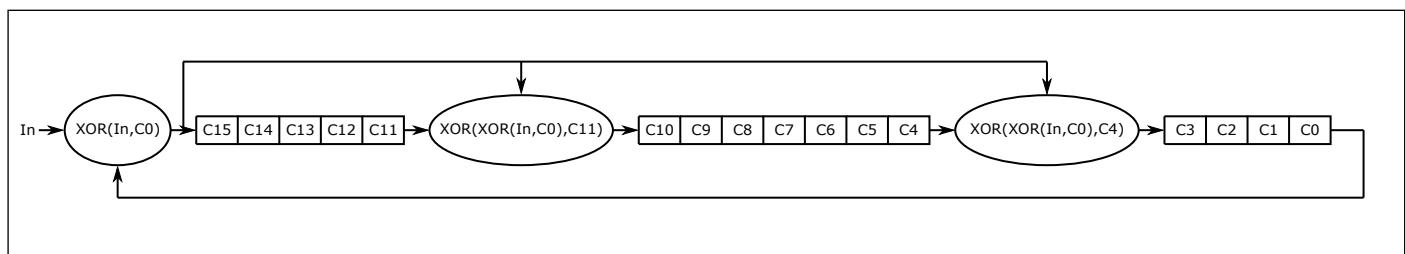

Fig. 12.32: CRC Calculation Method

The initial value of the 16-bit CRC generator before calculation is 0xFFFF, and the LSB of packet data is the first bit of the input CRC. The following figure illustrates the steps of CRC calculation by citing the data 0x01 as an example:

Step	In	XOR(In,C0)	C15	C14	C13	C12	C11	XOR(XOR(In,C0),C11(Step-1))	C10	C9	C8	C7	C6	C5	C4	XOR(XOR(In,C0),C4(Step-1))	C3	C2	C1	C0	C0
0	X	X	1	1	1	1	1	X	1	1	1	1	1	1	1	X	1	1	1	1	X
1	1(LSB)	0	0	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
2	0	1	1	0	1	1	1	0	0	1	1	1	1	1	1	0	0	1	1	1	1

Fig. 12.33: Example of CRC Calculation

12.3.7 Application Layer

This layer describes the higher-level encoding and interpretation of data contained in the data stream. Depending on the display subsystem architecture, it may consist of pixels or coded bit streams having a prescribed format, or of commands that are interpreted by the display controller inside a Display Module. The DSI specification describes the mapping of pixel values, bit streams, commands and command parameters to bytes in the packet assembly. (For more details, see the Display Command Set (DCS) specification, which will not be presented here).

12.3.8 Command Mode

Command Mode refers to that the interaction between MCU and peripherals including the display controller (such as Display Module) by sending commands and data. The display controller may include local registers and compressed or uncompressed frame buffers. Systems using Command Mode write to, and read from, the registers and frame buffer memory. The MCU indirectly controls the activities at peripherals by sending commands, parameters and data to the display controller. The MCU can also read Display Module status information or the contents of the frame memory. Command Mode operation requires a bidirectional interface.

12.3.9 Video Mode

Video Mode refers to operation in which the transfer from the MCU to the peripheral takes the form of a real-time pixel stream. The Display Module relies on the MCU to provide image data at sufficient bandwidth to avoid flicker or other visible artifacts in the displayed image. Video information can only be transmitted in the HS Mode. Video Mode involves three modes: NonBurst Mode with SYNC Pulses, NonBurst Mode with SYNC Events, and Burst Mode. The three modes have different packet sequences, and the timing requirements of peripherals determine which mode is appropriate.

12.3.9.1 Non-Burst Mode with SYNC Pulses

It enables the peripheral to reconstruct the original video timing accurately, including sync pulse widths. In this mode, the goal is to convey DPI-type timing over the DSI serial Link. It includes matching DPI pixel-transmission rates, and widths of timing events like sync pulses. Accordingly, synchronization periods are defined using packets transmitting both start and end of sync pulses. The following figure shows an example of the mode. Periods shown as Horizontal Sync Active (HSA), Horizontal Back Porch (HBP) and Horizontal Front Porch (HFP) are filled by the timing intervals in LP Mode. DSI switches from HS to LP Mode at the beginning of HSA, HBP and HFP, stays in the LP11 state during the periods, and switches back to HS Mode at the end:

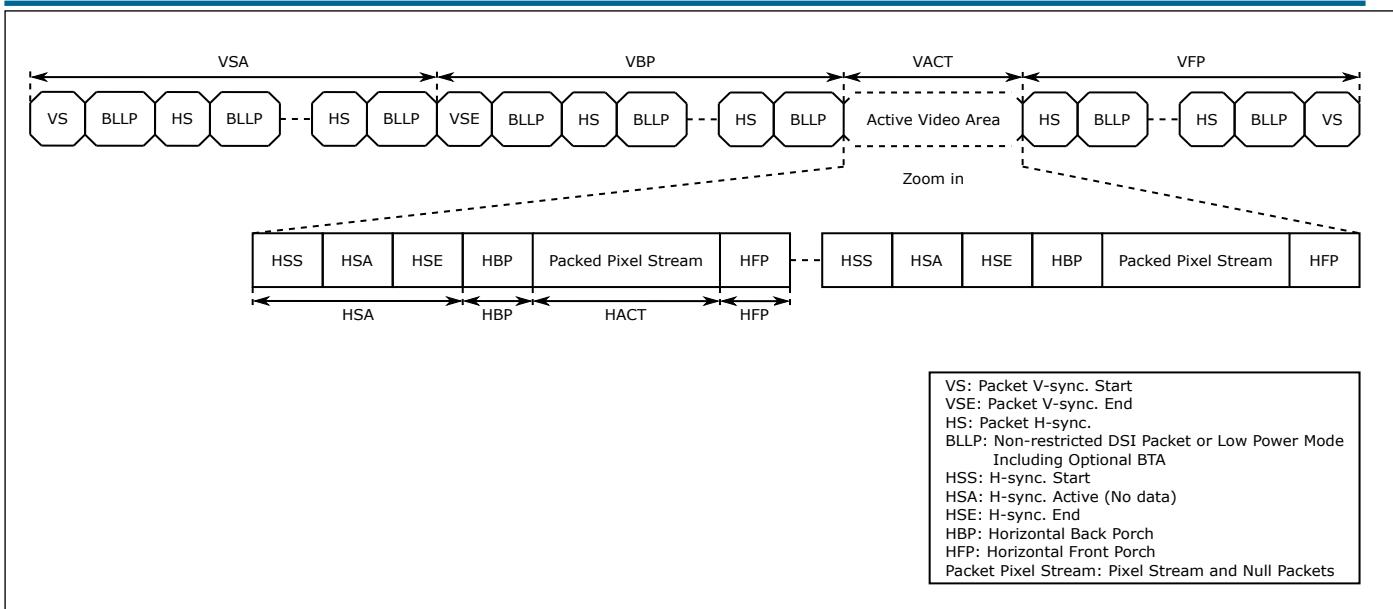

Fig. 12.34: Timing of NonBurst Mode with SYNC Pulses

12.3.9.2 Non-Burst Mode with SYNC Events

It is similar to the NonBurst Mode with SYNC Pulses. But an accurate reconstruction of sync pulse widths is not required, and hence the sync pulse is substituted by a single sync event, which is a simplification of the above NonBurst Mode with SYNC Pulses. In this mode, only the start of each sync pulse is transmitted. The peripheral may regenerate sync pulses as needed from each Sync Event packet received. Pixels are transmitted at the same rate as they would in a corresponding parallel display interface such as DPI-2. The following figure shows an example of the mode. Periods shown as Horizontal Sync Active (HSA), Horizontal Back Porch (HBP) and Horizontal Front Porch (HFP) are filled by the timing intervals in LP Mode. DSI switches from HS to LP Mode at the beginning of HSA, HBP and HFP, stays in the LP11 state during the periods, and switches back to HS Mode at the end:

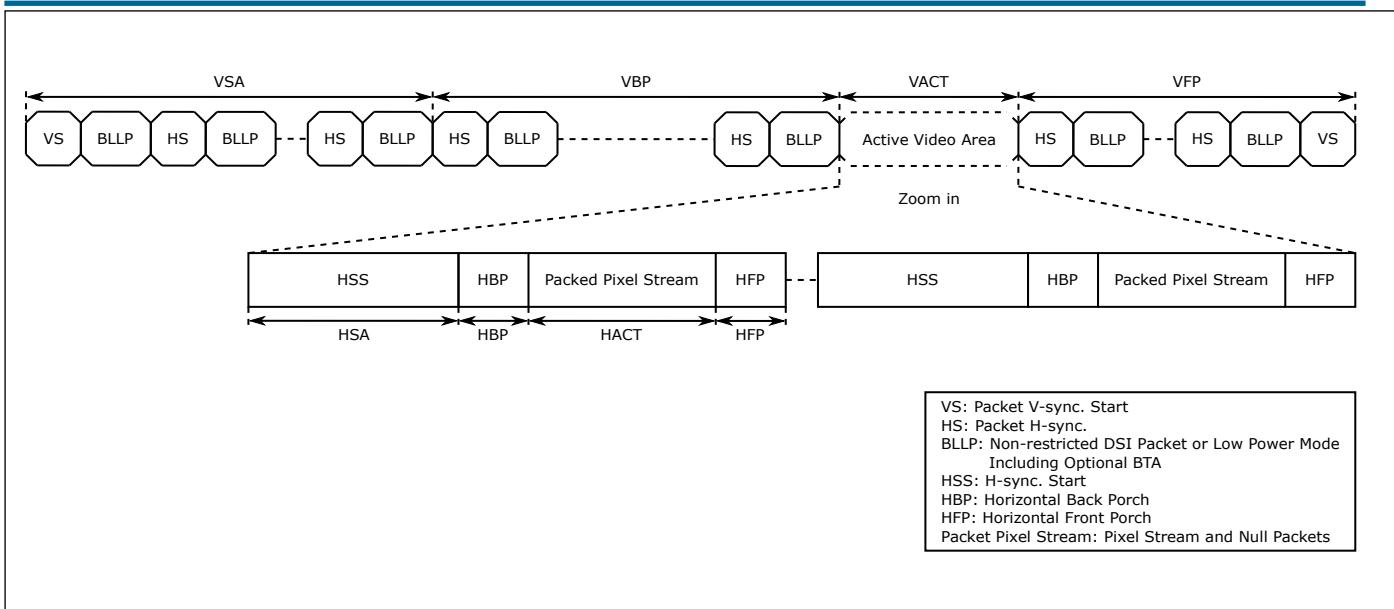

Fig. 12.35: Timing of NonBurst Mode with SYNC Events

12.3.9.3 Burst Mode

In this mode, the pixel packets are time-compressed, so that transmission can be completed in a short time. This strategy reduces overall DSI power consumption and enables larger blocks of time for other data transmissions over the Link in either direction. After the transmission of HS pixel data is completed, the bus switches to LP Mode. During this period, the bus may remain idle, i.e. staying in the LP11 state, or LP transmission can be performed in either direction. If the peripheral controls the bus that sends data to the MCU, its transmission time shall be limited to ensure that data will not flow from its internal buffer memory to the display device. The following figure shows an example of the mode. Periods shown as Horizontal Sync Active (HSA), Horizontal Back Porch (HBP) and Horizontal Front Porch (HFP) are filled by the timing intervals in LP Mode. DSI switches from HS to LP Mode at the beginning of HSA, HBP and HFP, stays in the LP11 state during the periods, and switches back to HS Mode at the end:

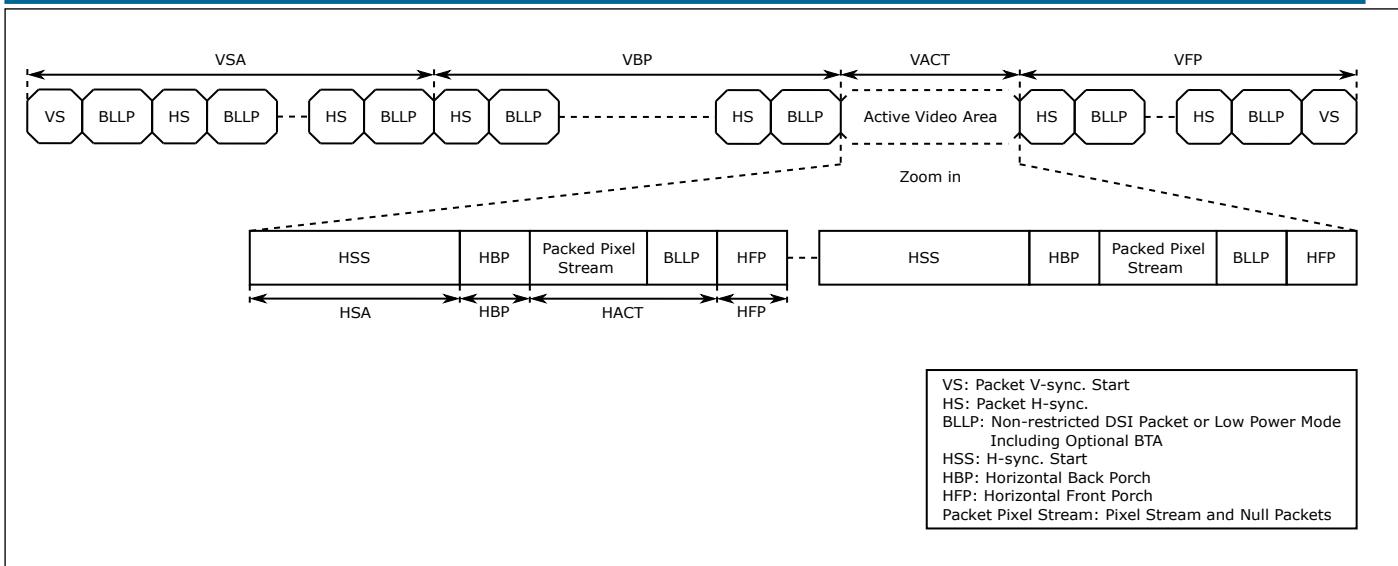

Fig. 12.36: Timing of Burst Mode

12.3.10 Line Buffer

Because the speed at which the frontend module inputs data to the DSI does not match the speed at which the DSI outputs data, it is necessary to buffer the data. Inside the DSI, there is a Line Buffer that can hold up to 1280*3 bytes and is used to cache the data input to the DSI in Video Mode. Users need to set a threshold through <CR_HSTX_OUT_TH>. Then, for each row (H-Sync) of image data in Video Mode, the DSI will not send the data immediately after receiving the data input from its frontend module, but will cache it in Line Buffer first. When the pixels cached in Line Buffer reach the set threshold, the DSI starts to send data to the Display Module. In this way, when the DSI's input speed is greater than the output speed, the input data that cannot be sent out timely will be cached in Line Buffer first. When that is lower than the output speed, Line Buffer will cache some data first, and the DSI will start sending data after the pixel threshold is met. This can ensure that the time of sending the whole row of pixels by the DSI matches the time of inputting the remaining pixels. The formula for calculating the threshold is as follows:

$$\text{Threshold} = \text{ceil}(\text{Width} * (1 - \text{Fdp} * \text{BPP} / \text{Fhs} / \text{LN}))$$

- ceil() is rounded up.
- Width is the number of pixels in one row of the image.
- Fdp is the work clock of the previous-level module of DSI (data input module dp_dvp_tscc of DSI).
- Byte Per Pixel (BPP) refers to the number of bytes in a pixel format, such as 3 for RGB888/RGB666 and 2 for RGB565/YUV422_8.
- Lane Number (LN) is the number of data lanes.
- Threshold is to be calculated and its minimum value is 6. When the calculated value is less than 6, it shall be set to 6.

12.3.11 Display Data Format

The display data formats support YUV422 (8-bit), RGB565, RGB666 (loosely packed), and RGB888, which are configured in <CR_DT>.

12.3.11.1 YUV422(8-bit)

In YUV422 (8-bit) format, the Y, U and V components of one pixel are 8 bits each, in which two pixels share a set of UV. The long packet in YUV422 (8-bit) format consists of 1-byte DI, 2-byte non-zero WC, 1-byte ECC, payload with length in WC bytes, and 2-byte CRC. With this format, pixel boundaries are aligned with some byte boundaries, and the value in WC shall be any non-zero value divisible by 4. The structure of a long packet in YUV422 (8-bit) format is shown as follows:

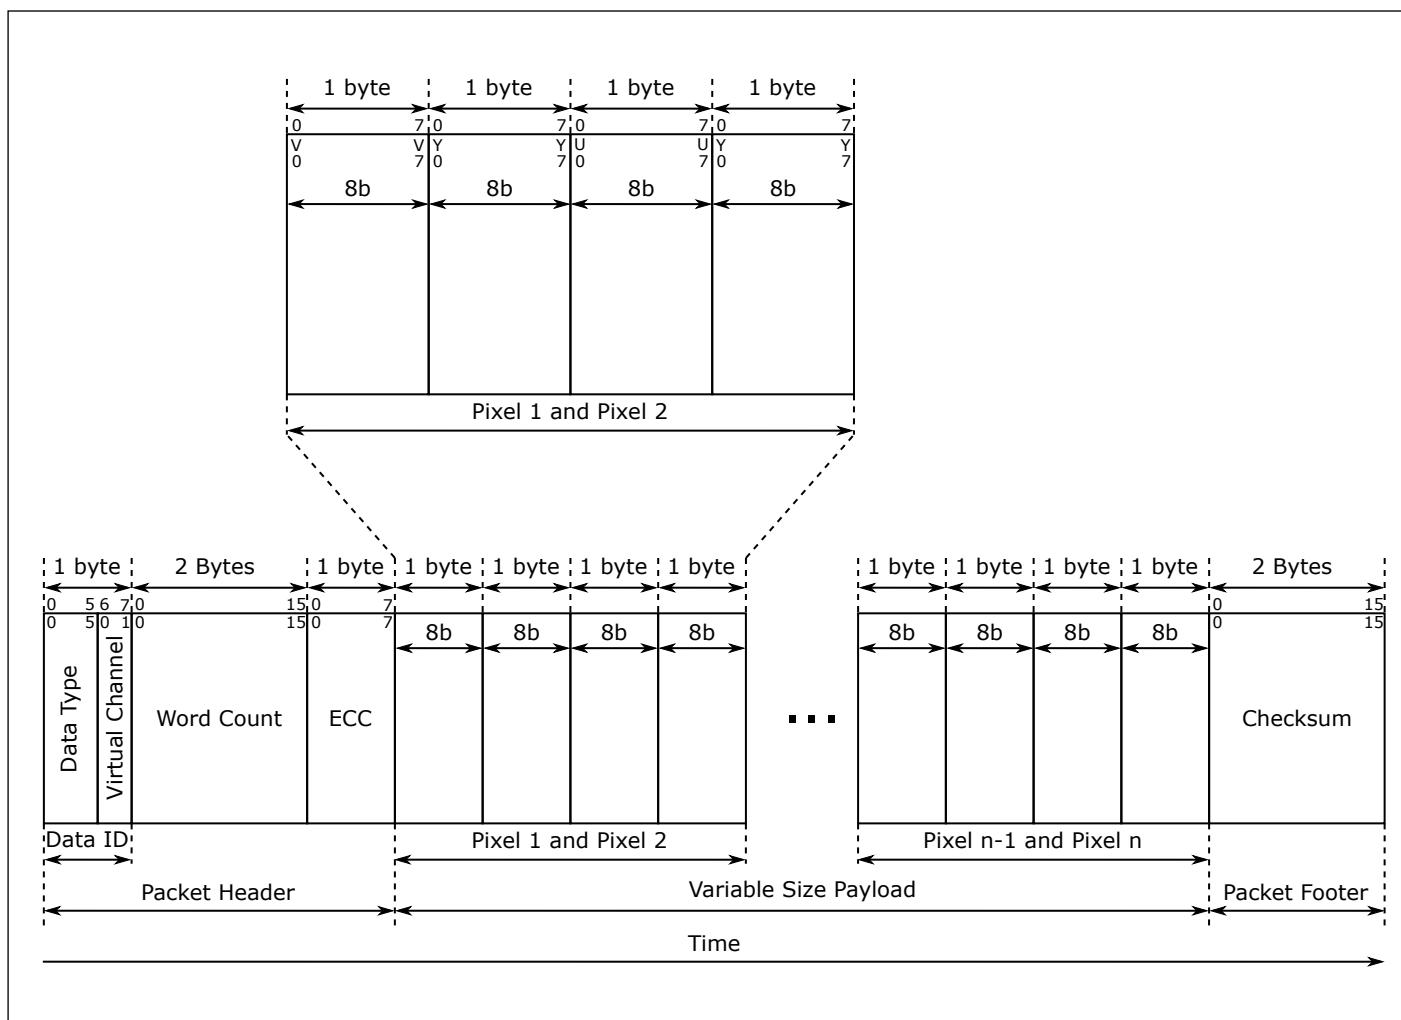

Fig. 12.37: YUV422 Pixel Format

12.3.11.2 RGB565

The R, G and B components of one pixel in RGB565 format are 5-bit, 6-bit and 5-bit respectively. The long packet in RGB565 format consists of 1-byte DI, 2-byte WC, 1-byte ECC, payload with length in WC bytes, and 2-byte CRC. With this format, the pixel boundary is aligned with the byte boundary every two bytes, and the value in WC shall be a multiple of 2. The structure of a long packet in RGB565 format is shown as follows:

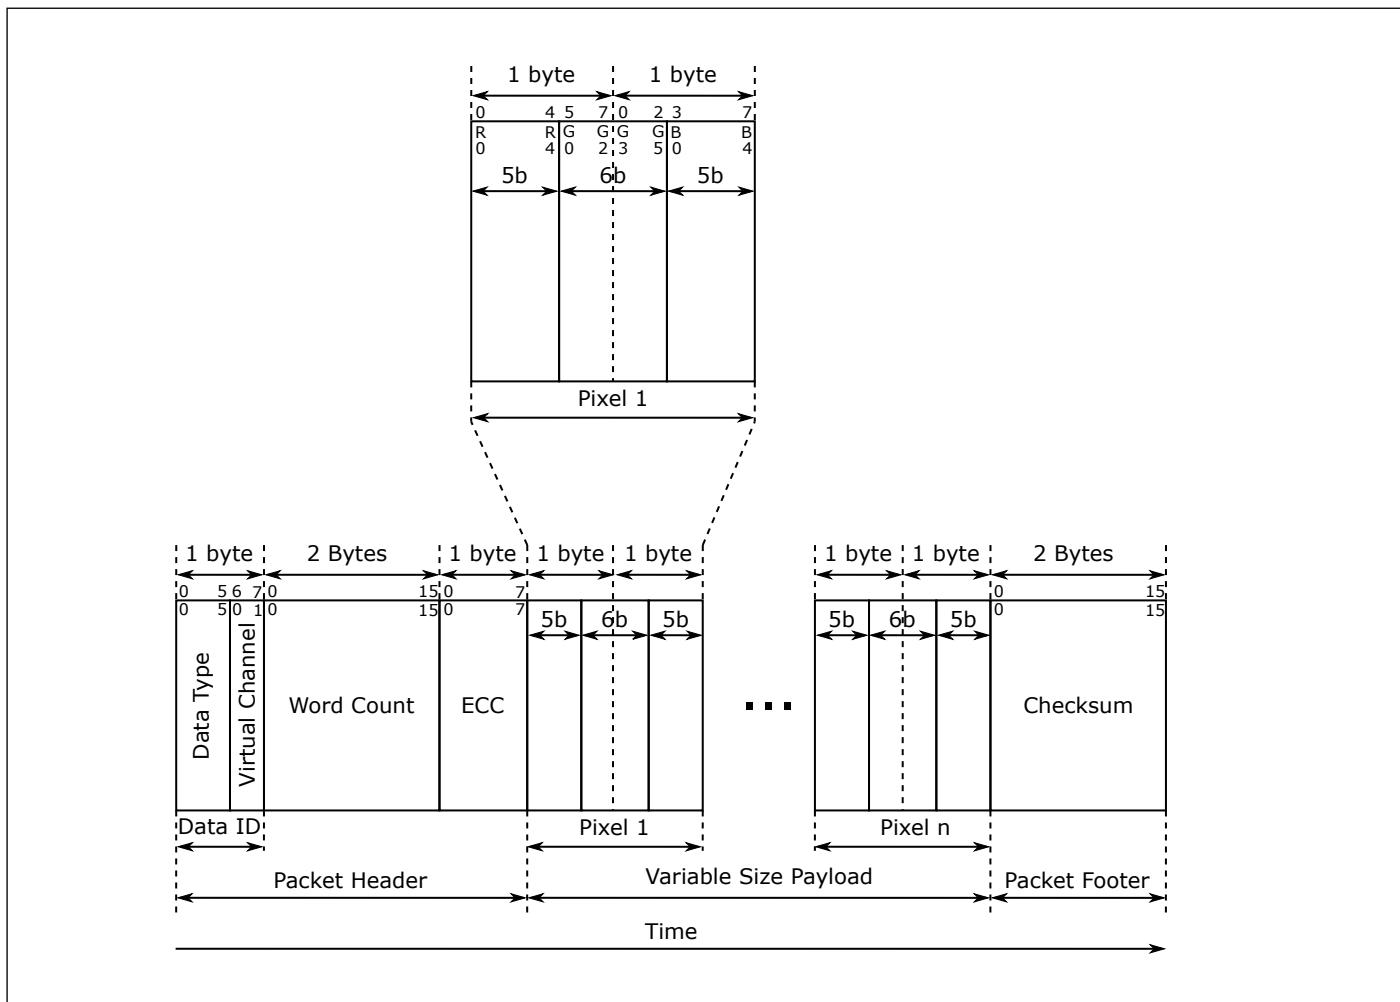

Fig. 12.38: RGB565 Pixel Format

12.3.11.3 RGB666(loosely packed)

The R, G and B components of one pixel in RGB666 (loosely packed) format are 6 bits each, but they will move to the high bit of the byte, so that the significant BPP occupies the bits [7:2] of each byte, while the bits [1:0] will be ignored. Accordingly, it takes three bytes for each pixel to be transmitted on the channel. The long packet in RGB666 format consists of 1-byte DI, 2-byte WC, 1-byte ECC, payload with length in WC bytes, and 2-byte CRC. With this format, the pixel boundary is aligned with the byte boundary every three bytes, and the value in WC shall be a multiple of 3. The structure of a long packet in RGB666 (loosely packed) format is shown as follows:

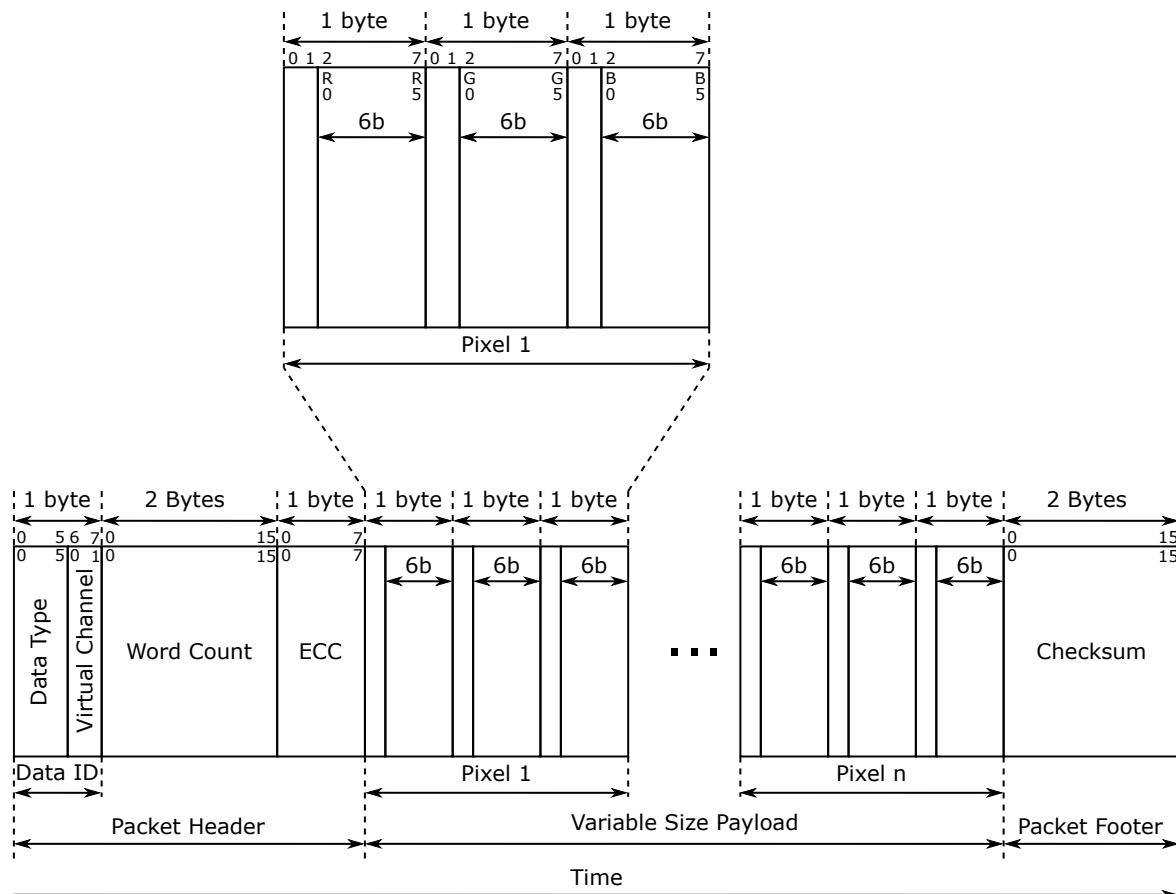

Fig. 12.39: RGB666 Pixel Format

12.3.11.4 RGB888

The R, G and B components of one pixel in RGB888 format are 8 bits each. The long packet in RGB888 format consists of 1-byte DI, 2-byte WC, 1-byte ECC, payload with length in WC bytes, and 2-byte CRC. With this format, the pixel boundary is aligned with the byte boundary every three bytes, and the value in WC shall be a multiple of 3. The structure of a long packet in RGB888 format is shown as follows:

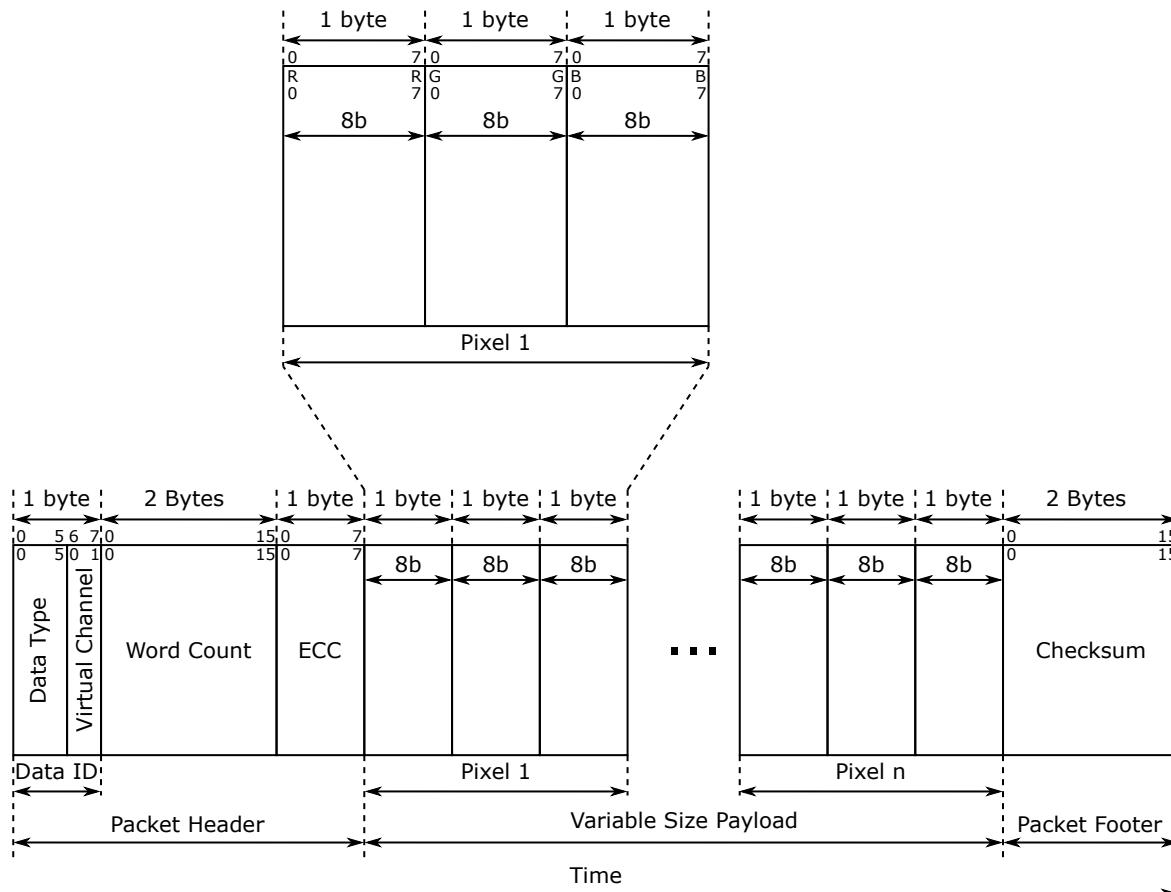

Fig. 12.40: RGB888 Pixel Format

12.3.12 Interrupt

DSI supports the following interrupts:

- TX Escape command end interrupt
- RX LPDT end interrupt
- RX ULPS command interrupt
- RX Trigger 0 command interrupt
- RX Trigger 1 command interrupt
- RX Trigger 2 command interrupt
- RX Trigger 3 command interrupt
- TX LPDT FIFO request interrupt
- RX LPDT FIFO request interrupt

- Buffer Overrun error interrupt
- Buffer Underrun error interrupt
- Too few pixel error interrupt
- Excessive pixel error interrupt
- FIFO overflow error interrupt

The TX Escape command end interrupt is triggered when any Escape command is sent.

RX LPDT end interrupt, RX ULPS command interrupt, RX Trigger 0 command interrupt, RX Trigger 1 command interrupt, RX Trigger 2 command interrupt, and RX Trigger 3 command interrupt will be triggered after the corresponding command is sent out and the ACK replied by the other side is received.

When TFICNT in DSI_FIFO_CONFIG_1 is greater than TFITH, the TX FIFO request interrupt will be generated, and the interrupt flag will be automatically cleared when the condition is not met.

When RFICNT in DSI_FIFO_CONFIG_1 is greater than RFITH, the RX FIFO request interrupt will be generated, and the interrupt flag will be automatically cleared when the condition is not met.

The Buffer Overrun error interrupt will be generated at Line Buffer Overrun, which means that the data cached in Line Buffer cannot be sent out timely and Line Buffer is full.

The Buffer Underrun error interrupt will be generated at Line Buffer Underrun, which means that the data in Line Buffer is completely read out and no new data is filled in timely.

The “too few pixel error interrupt” is generated when the number of pixels sent during HSync is smaller than the value configured by <CR_HSTX_PC>.

The “excessive pixel error interrupt” is generated when the number of pixels sent during HSync is greater than the value configured by <CR_HSTX_PC>.

The FIFO overflow error interrupt is generated in the case of Overflow or Underflow of TX or RX.

12.3.13 DMA

DSI LPDT supports the DMA transfer mode, which requires to set the thresholds of TX FIFO and RX FIFO respectively by configuring the <TFITH> and <RFITH> bits in the register DSI_FIFO_CONFIG_1. When this mode is enabled, if <TFICNT> is greater than <TFITH>, the DMA TX request is triggered. After DMA is configured, when receiving this request, DMA transfers data from memory to TX FIFO as configured. If <RFICNT> is greater than <RFITH>, the DMA RX request will be triggered. After DMA is configured, when receiving this request, DMA transfers the data in RX FIFO to the memory as configured.

12.3.14 Use with OSD

The input data of DSI can be configured to be processed by the OSD first. See the OSD Module section for functional description.

13.1 Overview

The Camera (CAM) module converts the parallel interface (DVP) into the general bus interface (AHB), and writes the pixel data generated by the image sensor into the system memory in a flat or packaged format for subsequent image transfer or compression. With flexible output format configuration, CAM can meet various image processing requirements.

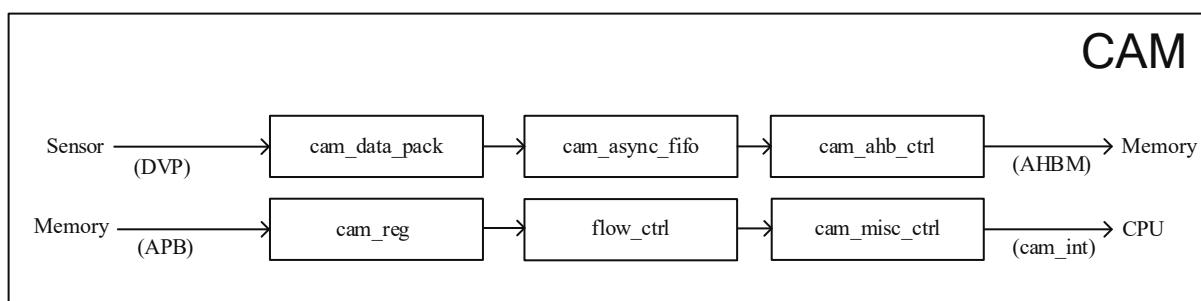

Fig. 13.1: Block Diagram of Cam

13.2 Features

- Parallel interface with 8-bit DVP signal, high-speed data transfer (80M), and configurable valid level and logical combination of DVP signal
- Supports 8-bit/16-bit/24-bit input pixel bit width
- Supports up to 36 data input sources
- Supports conversion of RGB888 input format to RGB565 or RGBA8888 output format
- Supports movie and photo modes
- Configurable discard modes:
 - Discard odd-bit data

- Discard even-bit data
- Discard odd-bit data of odd lines
- Discard even-bit data of odd lines
- Configurable line and frame synchronization signal selection and polarity selection of image sensor
- Supports rectangle cropping of image
- Supports integrity test of line and frame synchronization signals
- AHB bus communication interface
- FIFO with 512-byte cache to assist occasional busy bus
- Caches up to 4 images continuously
- Multiple application interrupts are beneficial to flexible use and error prompt

13.3 Functional Description

13.3.1 DVP(Digital Video Port) signal and configuration

Digital Video Port (DVP), a parallel interface, provides clock, frame synchronization, line synchronization, and 8-bit data pins. The clock limit is 80 MHz, so it is generally used for sensors with resolution below 5 MP. The active levels of frame and line synchronization can be independently configured on the chip, and four modes are provided on the valid data:

1. Frame synchronization and line synchronization are valid at the same time (" & " logic)
2. Either frame synchronization or line synchronization is valid (" | " logic)
3. Frame synchronization is valid
4. Line synchronization is valid

13.3.2 YCbCr Format

The luminance signal is also called Y signal. The chrominance signal is composed of two independent signals. Depending on the color system and format, the two chrominance signals are often called U & V, Pb & Pr, or Cb & Cr. They use different coding formats, but their concepts are essentially the same.

As there are more retinal rod cells that recognize brightness than the retinal cone cells that recognize chrominance in the human retina, human eyes are more sensitive to brightness than to chrominance. Thus, a part of chrominance information can be discarded without being perceived by human eyes.

The chrominance signal with the highest resolution is denoted as 4:4:4. That is, every 4-point Y sample corresponds to 4-point Cb and 4-point Cr samples. Similarly, 4:2:2 means that every 4-point Y sample corresponds to 2-point Cb and 2-point Cr samples. The number of scan lines of chrominance signal is as large as that of luminance signal, but

the chrominance sampling points on each scan line are only half of that of luminance signal. Different from the format described above, 4:2:0 does not mean that every 4-point Y sample corresponds to 2-point Cb and 0-point Cr samples, but means that every 4-point Y sample corresponds to 1-point Cb and 1-point Cr samples. The format 4:0:0 means discarding all the chrominance information, namely grayscale image.

13.3.3 Input Source

The data input source of CAM can be selected through configuration, and the relationship between configuration values and input sources is shown as follows:

Value	Input Type	Data Width	Value	Input Type	Data Width
1	Active DVP(TG)	8-bit	22	Adjust_1	16-bit
2	Defect Correct	8-bit	23	Adjust_2	16-bit
3	CCM_R	8-bit	24	Adjust_3	16-bit
4	CCM_G	8-bit	25	YUV420_0	16-bit
5	CCM_B	8-bit	26	YUV420_1	16-bit
6	Gamma_R	8-bit	27	YUV420_2	16-bit
7	Gamma_G	8-bit	28	YUV420_3	16-bit
8	-	-	29	Gamma_B	8-bit
9	BNR	8-bit	30	WDR_Y	8-bit
10	NR	16-bit	31	WDR_U	8-bit
11	EE	16-bit	32	WDR_V	8-bit
17	Scaler_0	16-bit	33	LSC	8-bit
18	Scaler_1	16-bit	34	AWB2	16-bit
19	Scaler_2	16-bit	35	YUV2RGB	24-bit
20	Scaler_3	16-bit	36	DVP_AS_2X	16-bit
21	Adjust_0	16-bit			

Fig. 13.2: Input Source Selection

13.3.4 Movie /Photo mode

In the photo mode, when the fixed-size memory provided by software is full, CAM will stop writing, and continue to write after the software performs POP operation for freeing up space.

In the movie mode, CAM will consecutively write in the fixed-size memory provided by software. That is, the memory will work as a ring buffer and no POP operation is required. In practice, it is necessary to ensure that images are taken out in real time or linked with the MJPEG module.

13.3.5 Rectangular Cropping of Image

You need to set the start and end positions for cropping line and frame synchronization signals by configuring the high 16 bits and low 16 bits of the registers HSYNC_CONTROL and VSYNC_CONTROL. Then, the image within the rectangular window marked based on the specified positions and size can be cropped and the remaining part beyond the window will be discarded. The start and end positions of the line synchronization signal are set by pixel numbers, while that of the frame synchronization signal are set by line numbers. The cropped image includes the start point but excludes the end point.

13.3.6 Integrity Test of Line and Frame Synchronization Signals

You can test the signal integrity by setting comparison values for line and frame synchronization signals respectively by configuring the low 16 bits and high 16 bits of the register FRAME_SIZE_CONTROL. The total number of pixels in each line is set for the line synchronization signal, and the total number of lines is set for the frame synchronization signal. When the count value of a line or frame synchronization signal of a frame of image is unequal to the comparison value, an interrupt will be generated.

13.3.7 Cached Image Information

The module has four FIFOs to record the address and size of images. Every time this module completely writes a frame into the memory, it will record the start address and image size of this frame of image in FIFO. However, when the memory is insufficient or four FIFOs are full, it will automatically discard the information of the incoming image. In the part where the image information has been taken out, the oldest image information will be removed by performing the pop operation through APB. Then, FIFO will automatically push data to ensure the timing of the image information in FIFO, as shown below:

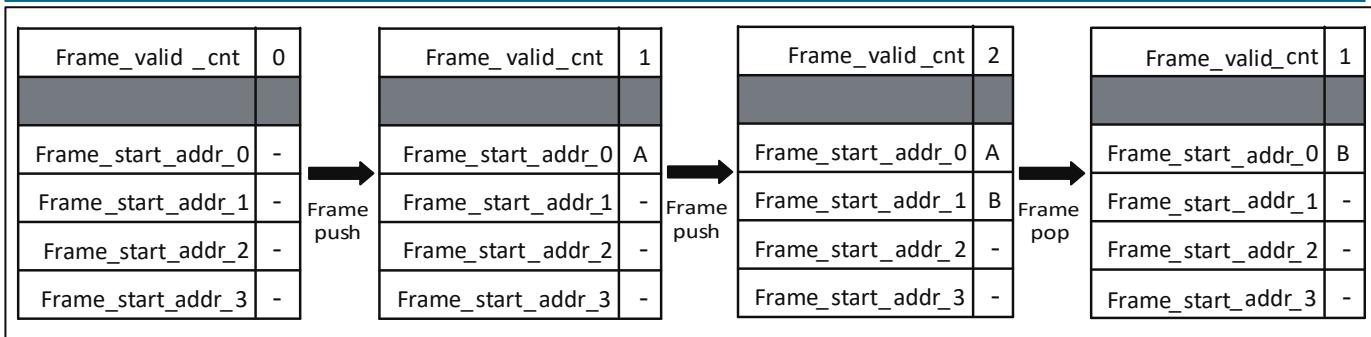

Fig. 13.3: FIFO Framework

13.3.8 Multiple Interrupts (Separately Configured)

- A. Normal interrupt: You can set to generate an interrupt after a fixed number of images are written
- B. Memory interrupt: When the memory is rewritten, an interrupt will be generated

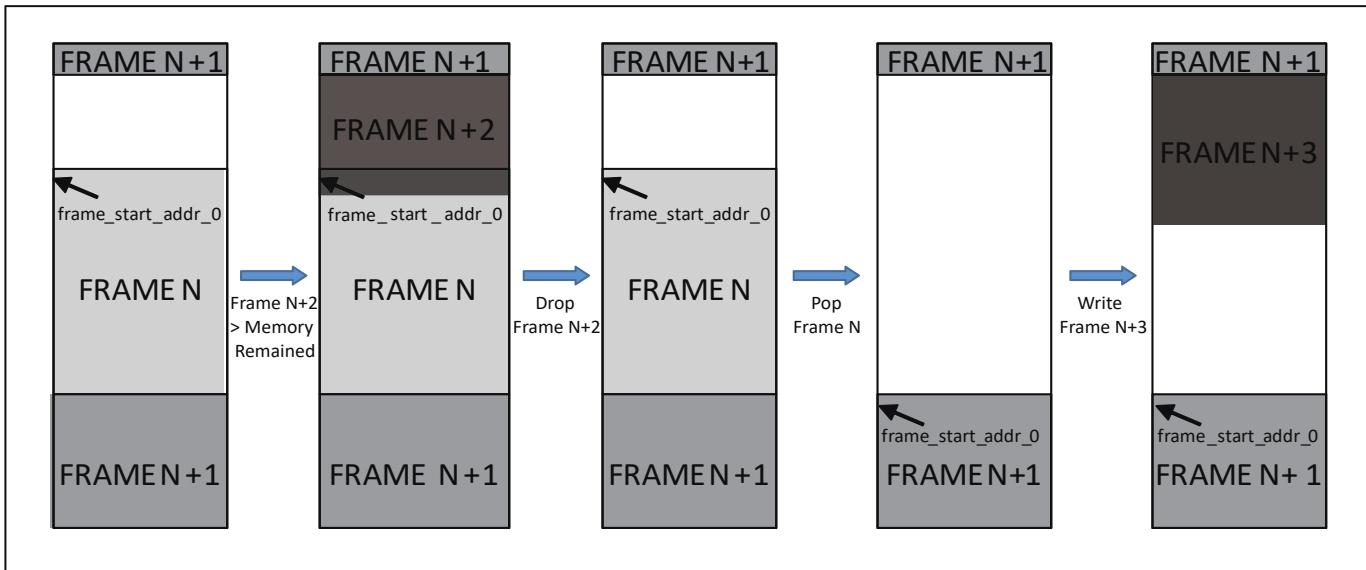

Fig. 13.4: Memory

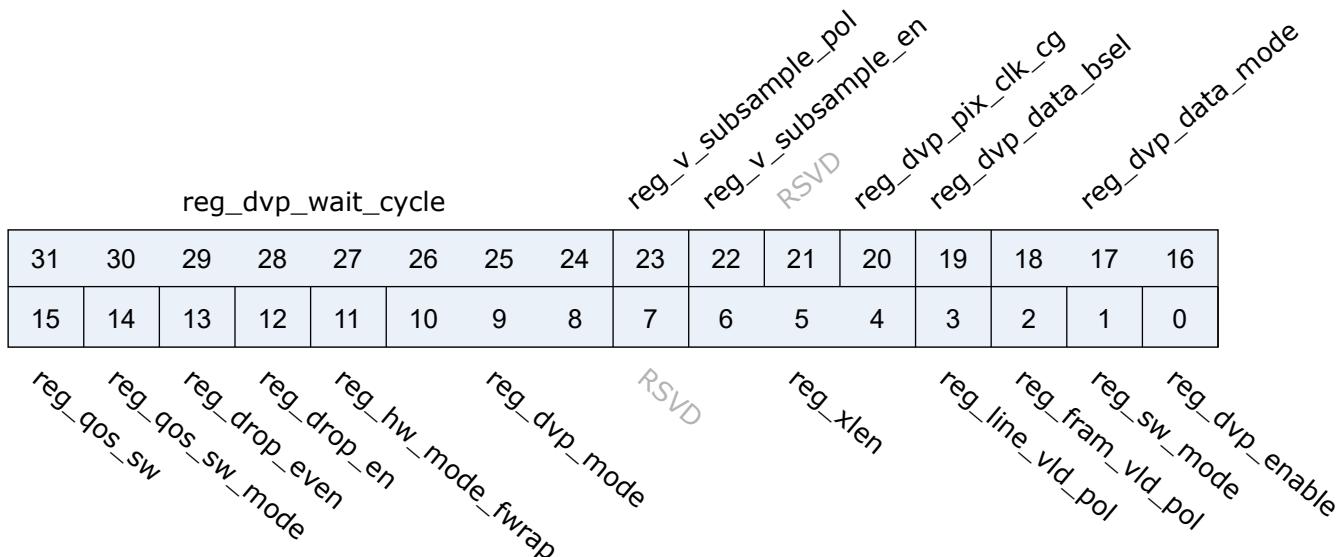

- C. Frame interrupt: When there are more than 4 unprocessed images, an interrupt will be generated
- D. FIFO interrupt: When the bus is too late to be written into memory and FIFO overflows, an interrupt will be generated
- E. Hsync interrupt: When the number of pixels in a line in a frame of image is unequal to the set value, an interrupt will be generated
- F. Vsync interrupt: When the total number of lines of a frame of image is unequal to the set value, an interrupt will be generated

IR

14.1 Overview

Infrared Remote Control (IR) is a wireless and non-contact control technique that features strong anti-interference, reliable information transmission, low power consumption, and low cost. The IR radiating circuit uses the IR LED to emit the modulated infrared waves. The receiving circuit consists of infrared receiving diodes, triodes or silicon photocells, which convert the infrared light emitted by the infrared transmitter into corresponding electrical signals, and then send them to the post amplifier.

14.2 Features

- Receives data through the fixed NEC and RC5 protocols
- Receives data in any format by pulse width counting
- With powerful infrared waveform editing capability: It can emit waveforms conforming to various protocols
- Up to 15-gear power settings to adapt to different power consumption requirements
- Receives up to 64-bit data
- Sends up to 128-bit data in the non-free mode and continuously sends the data of any length in the free mode
- 4*4 byte TX FIFO, 64*2 byte RX FIFO
- Adjustable width of the TX FIFO in the free mode (8/16/24/32-bit)
- Programmable carrier frequency and duty ratio
- Maximum operating frequency of 32 MHz
- Supports the DMA sending mode
- End of sending and receiving interrupts

14.3 Functional Description

14.3.1 Fixed Protocol Based Receiving

IR receiving supports the fixed NEC and RC5 protocols.

- NEC Protocol

Logical ‘1’ and logical ‘0’ waveforms of the NEC protocol are shown as follows:

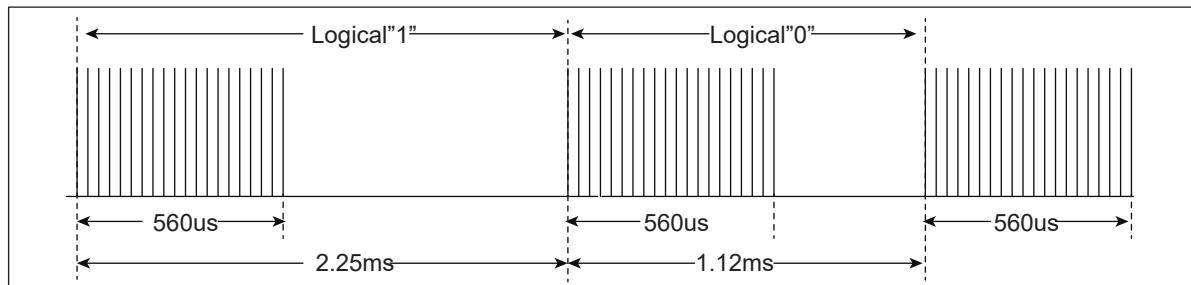

Fig. 14.1: NEC Logic Waveform

Logical ‘1’ is 2.25 ms and the pulse time is 560 us. Logical ‘0’ is 1.12 ms and the pulse time is 560 us. The format of the NEC protocol is shown as follows:

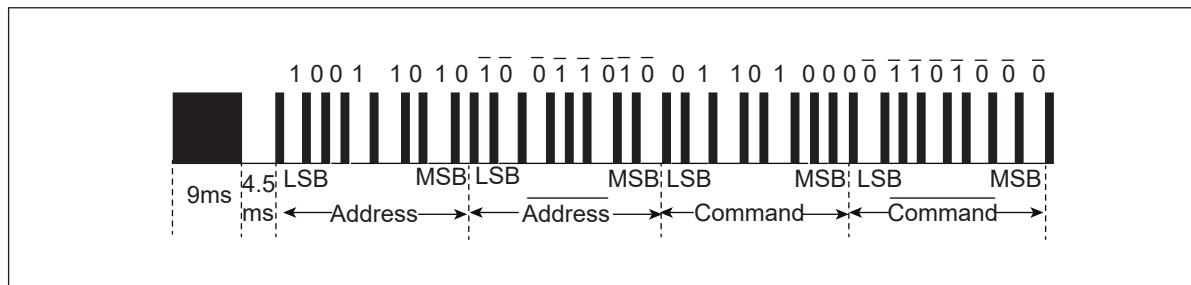

Fig. 14.2: NEC Protocol Waveform

The head pulse is a 9 ms high-level pulse and a 4.5 ms low-level pulse, followed by an 8-bit address code and its radix-minus-one complement (diminished radix complement), then an 8-bit command code and its radix complement, and the tail pulse is a 560 us high-level pulse and a 560 us low-level pulse.

- RC5 Protocol

Logical ‘1’ and logical ‘0’ waveforms of the RC5 protocol are shown as follows:

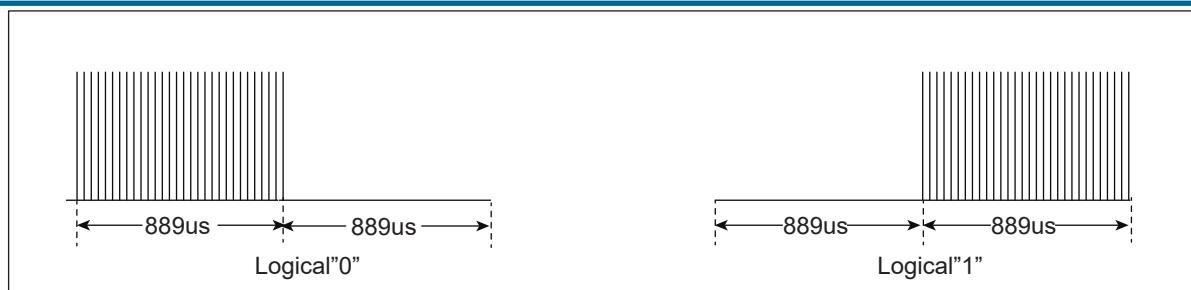

Fig. 14.3: RC5 Logic Waveform

The logical ‘1’ is 1.778 ms, first the 889 us low level and then the 889 us high level. Logical ‘0’ is opposite to the logical 1 waveform. The format of the RC5 protocol is shown as follows:

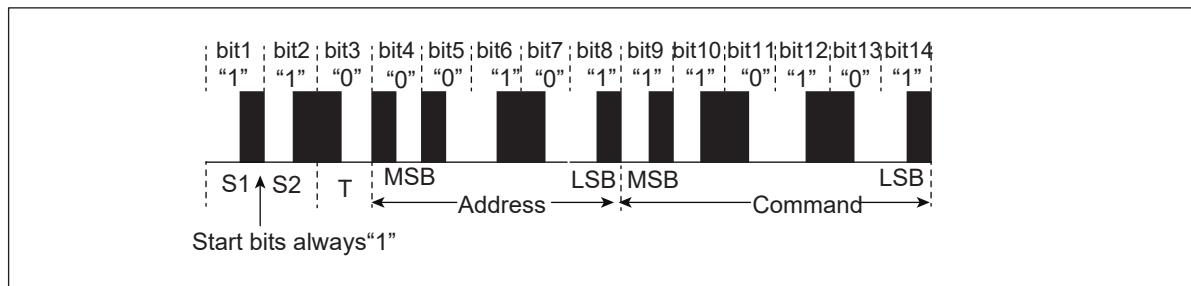

Fig. 14.4: RC5 Protocol Waveform

The first two bits are the Start bits, both logical ‘1’ . The third bit is the toggle bit, which toggles each time a key is released and pressed again. The next 5 bits are address bits and the next 6 bits are command bits.

It is worth noting that to improve the receiving sensitivity, the common infrared integrated receiver outputs a low level after receiving a high level, so you need to enable the receiving toggle function when using the IR receiving function.

14.3.2 Pulse width receiving

For data in any format other than the NEC and RC5 protocols, IR will count the duration of each high or low level in turn by its clock, and then store the data into the RX FIFO with a depth of 64 and a width of 2 bytes.

14.3.3 Normal sending mode

You can configure the head pulse, tail pulse, logical ‘0’ pulse, and logical ‘1’ pulse depending on protocols. During setting, you need to calculate the common pulse width unit—the greatest common divisor—of various pulses with different widths in the used protocol, fill it in the low 12 bits in the register IRTX_PULSE_WIDTH, and then fill the corresponding multiple of each pulse in the register IRTX_PW.

Then, you can fill the logic value to be sent into the TX FIFO with a depth of 4 and a width of 4 bytes.

14.3.4 Pulse width sending

IR provides a way of sending pulse width for the protocols that are unsuitable for the normal sending mode. You need to calculate the common pulse width unit—the greatest common divisor—of various pulses with different widths in the used protocol, and fill it in the low 12 bits in the register IRTX_PULSE_WIDTH. Then, for the multiples (8-bit per multiple) corresponding to each level width from the first high level to the last level, every four multiples are combined into a 32-bit number for padding in the TX FIFO.

14.3.5 Carrier modulation

Setting the high 16 bits of the register IRTX_PULSE_WIDTH can generate carriers with different frequencies and duty ratios. The <TXMPH1W> bit in the register is set to the width of carrier phase 1, while the <TXMPH0W> bit is set to the width of carrier phase 0.

14.3.6 Free mode

In the free mode, there is no limit to the total length of data to be sent. When there is data in TX FIFO, it will be sent, so it can be used with DMA. The width of TX FIFO in free mode can be configured to 8/16/24/32-bit.

14.3.7 DMA mode

IR TX supports the DMA mode, which requires to enable the free mode and set the threshold of TX FIFO by configuring <TFITH> in the register IRTX_FIFO_CONFIG_1.

When this mode is enabled, if <TFICNT> in the IRTX_FIFO_CONFIG_1 is greater than <TFITH>, the DMA TX request will be triggered. After DMA is configured, when receiving this request, DMA will transfer data from memory to TX FIFO as configured.

14.3.8 IR Interrupt

There are separate end of sending and receiving interrupts for IR, and when a sending action ends, a TX interrupt will be generated. When a piece of data is received, it will wait for the level duration to reach the preset end threshold before generating a receiving interrupt.

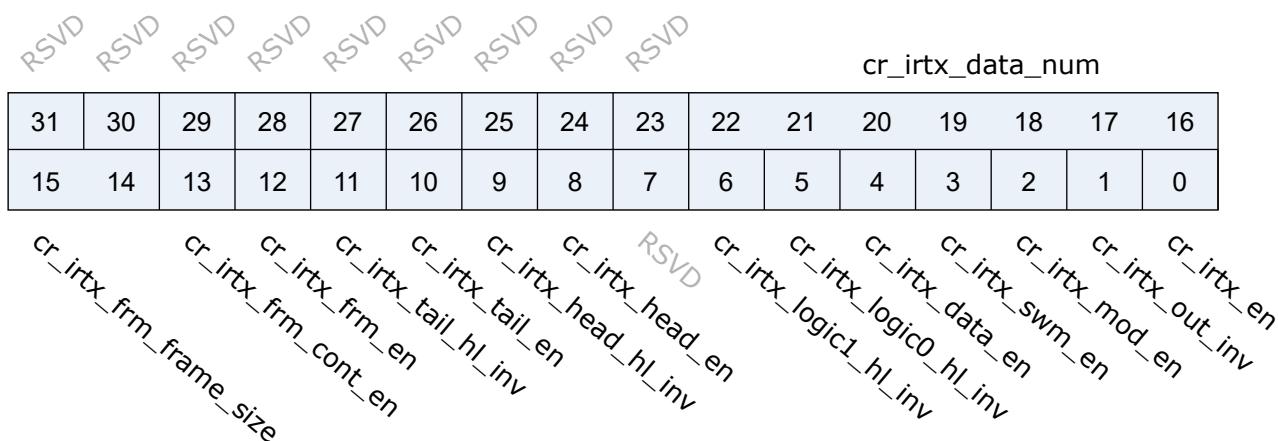

The register IRTX_INT_STS can query the TX interrupt status and clear the interrupt, and the register IRRX_INT_STS can query the receiving interrupt status and clear the interrupt.

15.1 Overview

Serial Peripheral Interface (SPI) Bus is a synchronous serial communication interface specification for short-range communication. Devices communicate in the full duplex mode, which is a master-slave mode where one master controls one or more slaves.

SPI completes full-duplex communication with 4 signal lines, namely CS (chip select), SCLK (clock), MOSI (master output slave input), and MISO (master input slave output).

15.2 Features

- Can be used as SPI master or slave
- Both master and slave support 4 clock formats (CPOL, CPHA)
- Both master and slave support 1/2/3/4-byte transfer mode
- The sending and receiving channels each have a FIFO with a depth of 32 bytes
- The adaptive FIFO depth variation characteristic suits high-performance applications
 - When the Frame is 32Bits, the depth of FIFO is 8
 - When the Frame is 24Bits, the depth of FIFO is 8
 - When the Frame is 16Bits, the depth of FIFO is 16
 - When the Frame is 8Bits, the depth of FIFO is 32
- Configurable MSB/LSB transfer
- Adjustable byte transfer sequence
- Flexible clock configuration, which supports up to 80M clock

- Configurable MSB/LSB transfer priority
- Receive ignore function: You can set to ignore the reception of data from the specified location
- Supports timeout mechanism in the slave mode
- Supports DMA transfer mode

15.3 Functional Description

15.3.1 Clock Control

Due to different clock phases and polarity settings, the SPI clock has four modes, which can be set by cr_spi_sclk_pol (CPOL) and cr_spi_sclk_ph (CPHA) in the register spi_config. CPOL determines the level of SCK clock signal when it is idle. If CPOL=0, the idle level is low, and if CPOL=1, the idle level is high. CPHA determines the sampling time. If CPHA=0, sampling is made at the first clock edge of each cycle, and if CPHA=1, that is made at the second clock edge of each cycle.

By setting the registers spi_prd_0 and spi_prd_1, you can also adjust the duration of the start and end levels of the clock, time of phase 0/1, and interval between frames of data. The settings of the four modes are shown as follows:

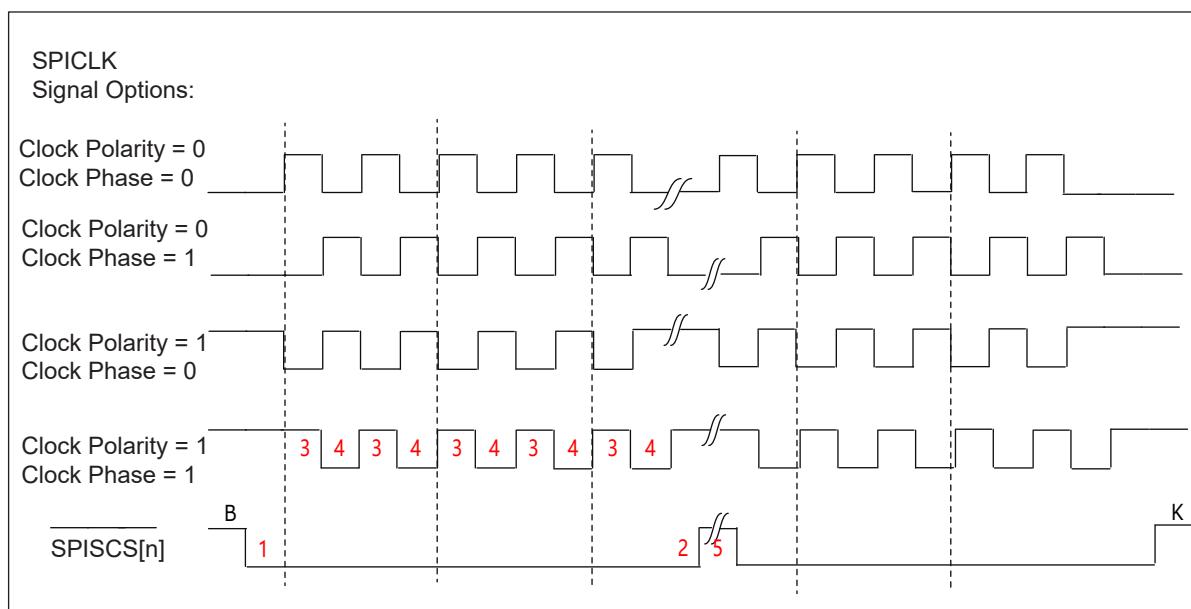

Fig. 15.1: SPI Timing

The meanings of numbers are as follows:

- “1” denotes the length of the START condition, which is configured by the cr_spi_prd_s in the register spi_prd_0.
- “2” denotes the length of the STOP condition, which is configured by the cr_spi_prd_p in the register spi_prd_0.
- “3” denotes the length of phase 0, which is configured by the cr_spi_prd_d_ph_0 in the register spi_prd_0.
- “4” denotes the length of phase 1, which is configured by the cr_spi_prd_d_ph_1 in the register spi_prd_0.

- “5” denotes the interval between frames of data, which is configured by the cr_spi_prd_i in the register spi_prd_1.

15.3.2 Master Continuous Transfer Mode

After this mode is enabled, the CS signal will not be released when the current data is sent and there are still available data in FIFO.

15.3.3 Master-Slave: Transfer and Receive Data

The same framesize shall be set for the master and slave for transferring and receiving data by configuring the cr_spi_frame_size in the register spi_config. When the master and slave agree to communicate at a 32 bits framesize, if the clk of the master does not meet 32 bits due to an exception in a frame of data, the following symptoms occur.

- The data sent by the master cannot be transferred to the RX FIFO of the slave. The slave cannot receive data from the master.
- When the slave sends data, it will skip this frame of data and continue to send the next frame of data when the master’s clk is normal again.

15.3.4 Receive Ignore Function

When the start and end bits to be filtered out are set, SPI will discard the corresponding data segments in the received data, as shown below:

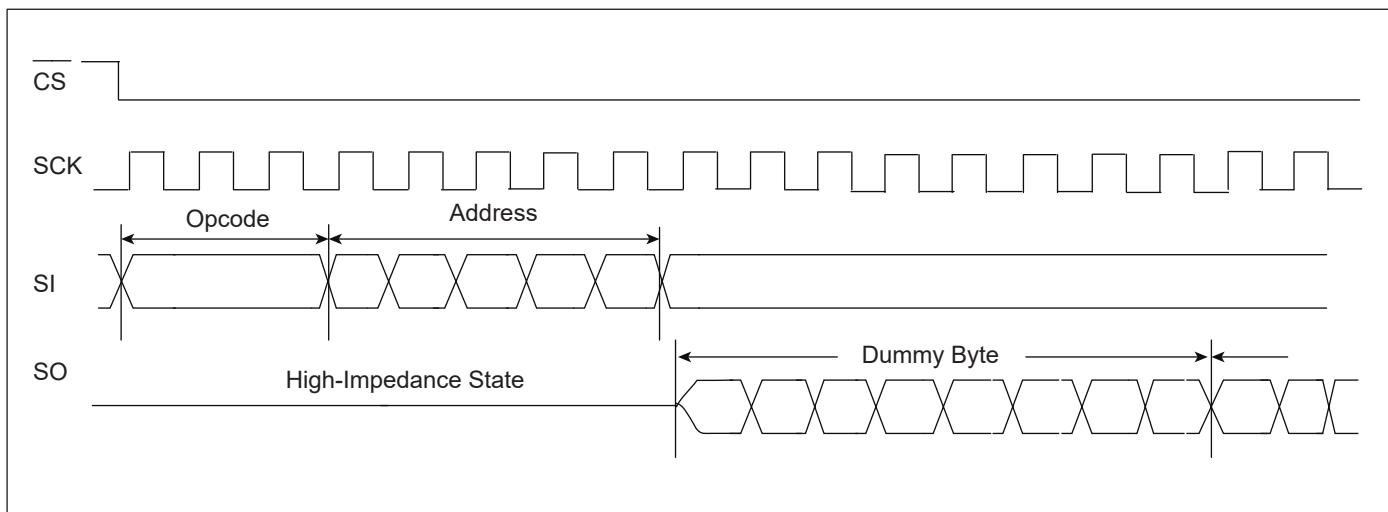

Fig. 15.2: SPI Ignore Waveform

You can enable this function by configuring the cr_spi_rxd_ignr_en in the register spi_config. The start bit of this function is set by configuring the cr_spi_rxd_ignr_s in the register spi_rxd_ignr. The end bit of this function is set by configuring the cr_spi_rxd_ignr_p in the register spi_rxd_ignr.

In the above figure, the start bit to be filtered is set to 0, and if the end bit is set to 7, Dummy Byte will be received; if the end bit is set to 15, Dummy Byte will be discarded.

15.3.5 Filtering Function

When this function is enabled and a threshold is set, SPI will filter the data less than or equal to the width threshold.

When this function is enabled by setting the cr_spi_deg_en in the register spi_config and the threshold is set by configuring the cr_spi_deg_cnt, SPI will filter out the data that cannot reach the width threshold. The data width shall be less than cr_spi_deg_cnt+1: As shown in the figure below, when the data width is 4, setting the cr_spi_deg_cnt to 4 can meet this condition. “Input” is the initial data and “output” is the filtered data.

Filtering logic process:

- “Tgl” is the exclusive OR result of input and output.
 - “Deg_cnt” counts from 0, and the counting condition is that “tgl” is at the high level and “reached” is at the low level.
 - “Reached” means whether the current deg_cnt count reaches the set cr_spi_deg_cnt, and it is at a high level once reached.
 - When “reached” is at a high level, “input” is output to “output” .
 - Note: user-defined condition for deg_cnt: “tgl” is at a high level and “reached” is at a low level. In other cases, “deg_cnt” will be cleared to 0.

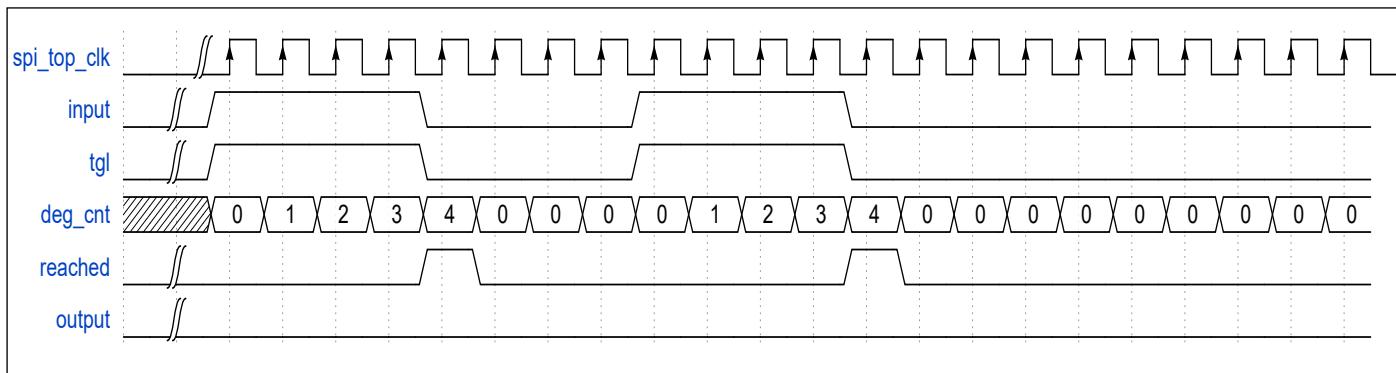

Fig. 15.3: SPI Filter Waveform

15.3.6 Configurable MSB/LSB Transfer

The configurable MSB/LSB transfer mode is limited to the priority transfer sequence of 8 bits in one byte, and the transfer sequence of bits in one byte is set by configuring the cr_spi_bit_inv bit in the register spi_config. 0 indicates MSB and 1 indicates LSB.

For example, for data transfer where the frame size is 24 bits, the data format is Data[23:0]=0x123456.

When MSB transfer is set, the transfer sequence is: 01010110 (binary, 1st byte: 0x56); 00110100 (binary, 2nd byte: 0x34); 00010010 (binary, 3rd byte: 0x12). When LSB transfer is set, the transfer sequence is: 01101010 (binary, 1st byte: 0x56); 00101100 (binary, 2nd byte: 0x34); 01001000 (binary, 3rd byte: 0x12).

15.3.7 Adjustable Byte Transfer Sequence

The adjustable byte transfer sequence is limited to the priority transfer sequence between different bytes in FIFO. The transfer sequence of bytes in FIFO is set by configuring the cr_spi_byte_inv bit in the register spi_config. 0 means sending LSB first, and 1 means sending MSB first.

For example, for data transfer where the frame size is 24 bits, the data format is Data[23:0]=0x123456.

When LSB transfer priority is set, the transfer sequence is 0x56 (1st byte: LSB); 0x34 (2nd byte: intermediate byte); 0x12 (3rd byte: MSB). When MSB transfer priority is set, the transfer sequence is 0x12 (3rd byte: MSB); 0x34 (2nd byte: intermediate byte); 0x56 (1st byte: LSB).

Adjustable byte transfer can be used in conjunction with configurable MSB/LSB transfer.

15.3.8 Slave Mode Timeout Mechanism

When a timeout threshold is set, an interrupt will be triggered when SPI in the slave mode receives no clock signal after the threshold exceeds.

15.3.9 I/O Transfer Mode

The chip communication processor can perform FIFO padding and clearing operations in response to the interrupt from the FIFO. Each FIFO has a programmable FIFO trigger threshold to trigger an interrupt. When rx_fifo_cnt in the register spi_fifo_config_1 is greater than the trigger threshold of rx_fifo_th, an interrupt will be generated to send a signal to the chip communication processor to clear the RX FIFO. When rx_fifo_cnt in the register spi_fifo_config_1 is greater than rx_fifo_th, an interrupt will be generated to send a signal to the chip communication processor to re-pad the TX FIFO.

You can query the SPI status register to determine the sampled value in the FIFO and the FIFO status. The software must provide correct trigger thresholds for RX FIFO and TX FIFO, and prevent the overflow of RX FIFO and the underflow of TX FIFO.

15.3.10 DMA Transfer Mode

SPI supports the DMA transfer mode. To enable this mode, you must set the thresholds of TX FIFO and RX FIFO respectively. Setting spi_dma_tx_en in the register spi_fifo_config_0 to 1 can enable the DMA sending mode. Setting spi_dma_rx_en in the register spi_fifo_config_0 to 1 can enable the DMA receiving mode. When this mode is enabled, UART will check the TX/RX FIFO. Once the tx_fifo_cnt/rx_fifo_cnt in the register spi_fifo_config_1 is greater than tx_fifo_th/rx_fifo_th, a DMA request will be initiated, and DMA will transfer data into TX FIFO or remove data from RX FIFO as configured.

15.3.11 SPI Interrupt

SPI supports the following interrupt control modes:

- SPI end of transfer interrupt
- TX FIFO request interrupt
- RX FIFO request interrupt
- Slave mode transfer timeout interrupt
- Slave mode TX overload interrupt
- TX/RX FIFO overflow interrupt

In the master mode, the SPI end of transfer interrupt will be triggered when the transfer of each frame of data ends.

In the slave mode, that interrupt is triggered when the CS signal is released. The TX/RX FIFO request interrupt will be triggered when the FIFO available count value is greater than the preset threshold, and the interrupt flag will be cleared automatically when the condition is unmet. The slave mode transfer timeout interrupt will be triggered when no clock signal is received in the slave mode after the threshold exceeds. If the TX/RX FIFO overflows or underflows, it will trigger the TX/RX FIFO overflow interrupt. When the tx_fifo_clr/rx_fifo_clr bit in the FIFO clear register spi_fifo_config_0 is set to 1, the corresponding FIFO will be cleared and the overflow interrupt flag will be cleared automatically.

You can query the interrupt status through the register SPI_INT_STS and write 1 to the corresponding bit to clear the interrupt.

UART

16.1 Overview

The Universal Asynchronous Receiver/Transmitter (UART) provides a flexible way to exchange full-duplex data with external devices. BL808 is provided with four UARTs, which can be used together with DMA to achieve efficient data communication.

16.2 Features

- Full-duplex asynchronous communication
- Optional data bit length: 5/6/7/8-bit
- Optional stop bit length: 0.5/1/1.5/2-bit
- Supports odd/even/none check bit
- Error-detectable start bit
- Abundant interrupt control modes
- Hardware flow control (RTS/CTS)
- Convenient baud rate programming
- Configurable MSB/LSB transfer priority
- Automatic baud rate detection of ordinary/fixed characters
- 32-byte TX/RX FIFO
- Supports DMA transfer mode
- Supports baud rate of 10 Mbps and above
- Supports the LIN bus protocol

- Supports the RS485 mode
- Optional clock sources: 160M/BCLK/XCLK
- Support filter function

16.3 Functional Description

16.3.1 Data Formats

The normal UART communication data consists of start bits, data bits, parity check bits, and stop bits. The UART of xx supports configurable data bits, parity check bits, and stop bits, which are set in registers utx_config and urx_config. The waveform of a frame of data is shown as follows:

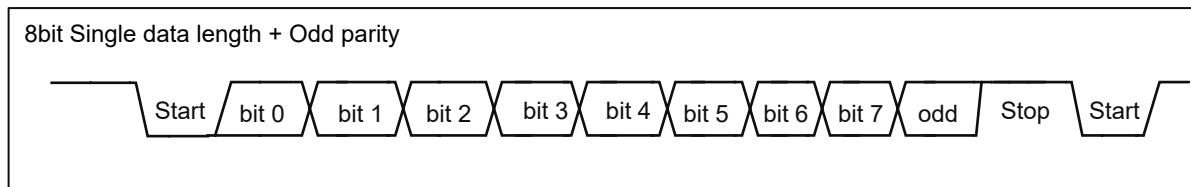

Fig. 16.1: UART Data Format

The start bit of the data frame occupies 1 bit, and the stop bit can be 0.5/1/1.5/2-bit wide by configuring the cr_utx_bit_cnt_p bit in the register utx_config. The start bit is at a low level and the stop bit is at a high level. The data bit width can be set to 5/6/7/8-bit by the cr_utx_bit_cnt_d bit in the register utx_config.

When the cr_utx_prt_en bit in the register utx_config and the cr_urx_prt_en bit in the register urx_config are set, the data frame adds a parity check bit after the data. The cr_utx_prt_sel bit in the register utx_config and the cr_urx_prt_sel bit in the register urx_config are used to select odd or even parity check. When the receiver detects the check bit error of the input data, it will generate the check error interrupt. However, the received data will still be stored into the FIFO.

Calculation method of odd parity check: If there is an odd number of “1” in the current data bit, the odd parity check bit is set to 0. Otherwise, it is set to 1.

Calculation method of even parity check: If there is an odd number of “1” in the current data bit, the even parity check bit is set to 1. Otherwise, it is set to 0.

16.3.2 Basic Architecture

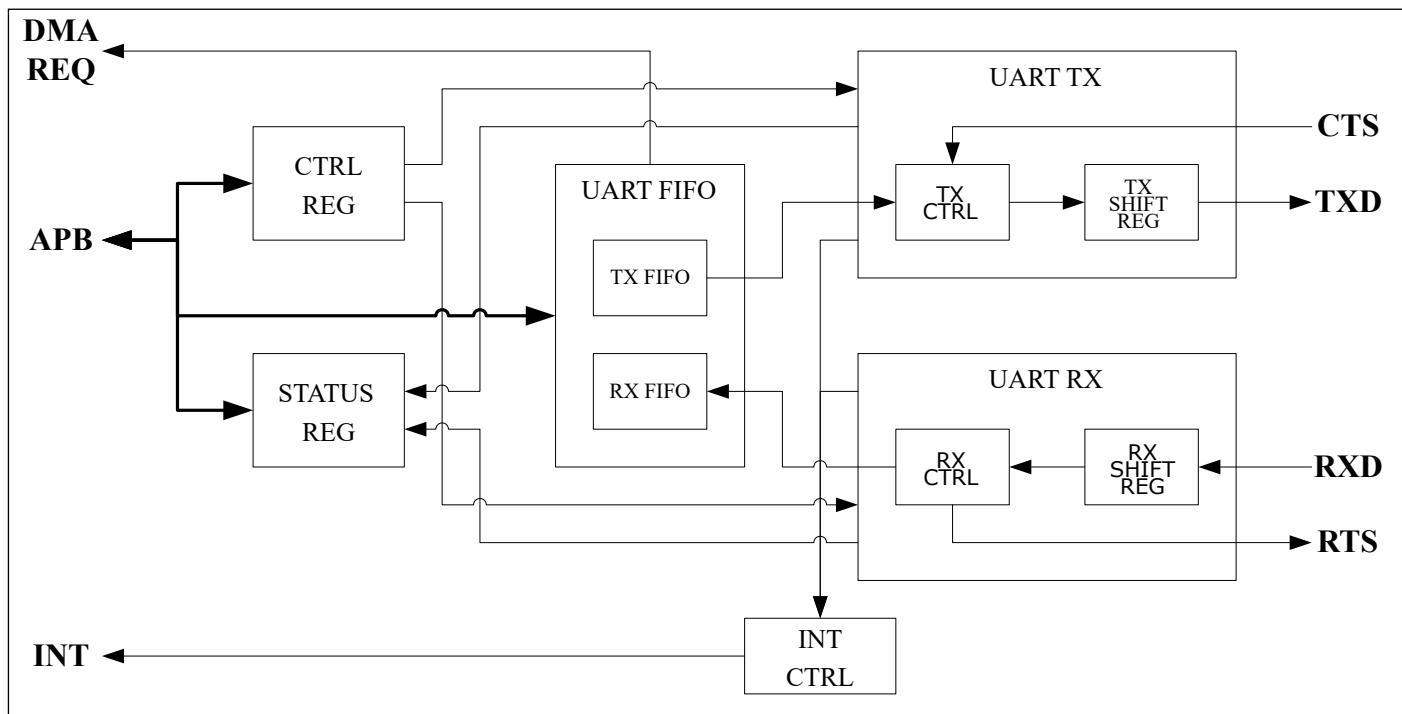

Fig. 16.2: UART Architecture

16.3.3 Clock Source

UART's clock sources include XCLK, 160 Mhz CLK, and BCLK. The frequency divider in the clock is used to divide the clock source and then generate the clock signal to drive UART, as shown below:

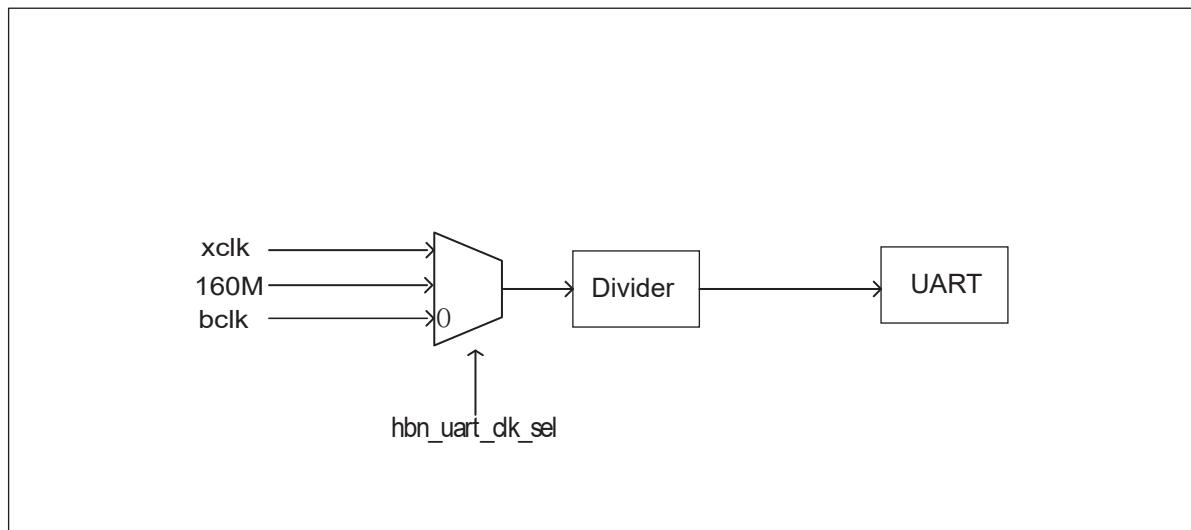

Fig. 16.3: UART clock

16.3.4 Baud Rate Setting

The user can set the register UART_BIT_PRD to generate the required baud rate. The high 16 bits cr_urx_bit_prd and low 16 bits cr_utx_bit_prd of this register correspond to RX and TX respectively. That is, the baud rates of RX and TX can be set separately. The 16 bits value is calculated by the following formula: baud rate = UART clock/(16-bit width factor + 1), that is, 16-bit width factor = UART clock/baud rate-1. This factor means the count value obtained by counting the bit width of the current baud rate with UART clock. Since the maximum 16-bit width factor is 65535, the minimum baud rate supported by UART is UART clock/65536.

Before sampling the data, UART will filter the data to remove the burrs in the waveform. Then, the data will be sampled at the intermediate value of the 16-bit width factor, so that the sampling time can be adjusted based on baud rates, to ensure that the intermediate value is always sampled, providing much higher flexibility and accuracy. The sampling process is shown as follows:

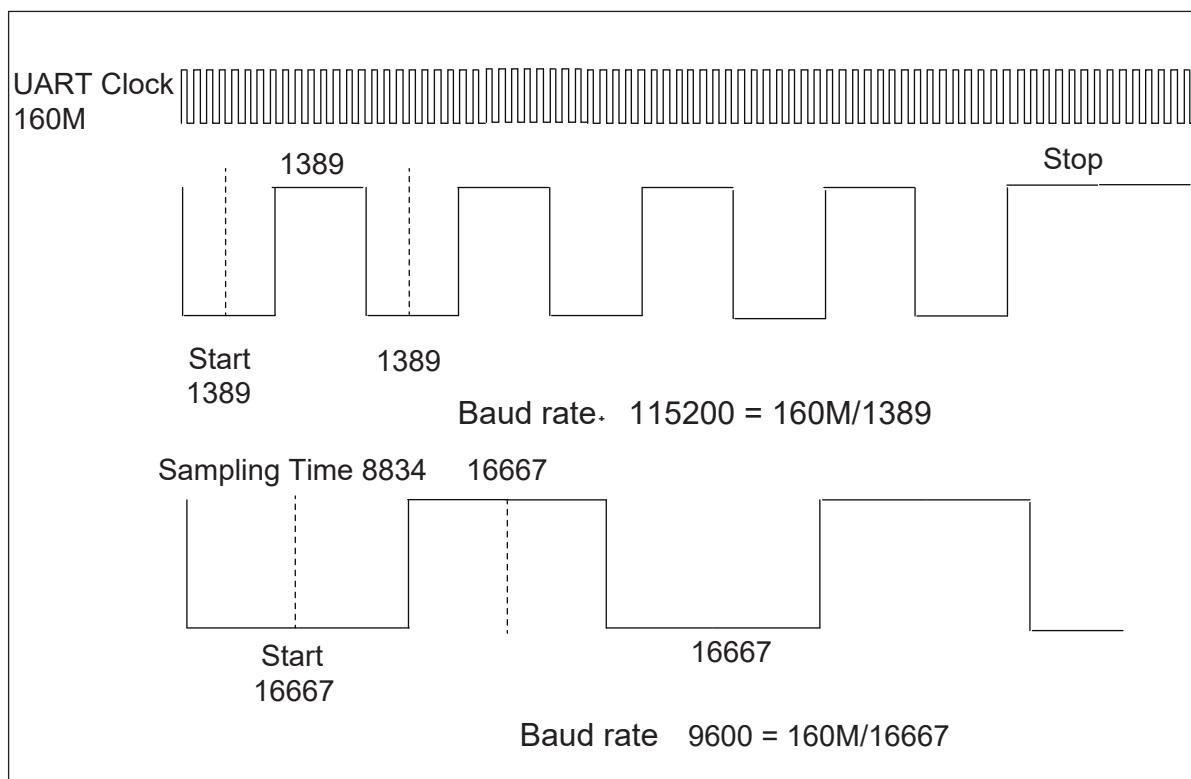

Fig. 16.4: UART Sampling Waveform

16.3.5 Filtering

When this function is enabled by configuring cr_urx_deg_en and the threshold is set by configuring cr_urx_deg_cnt in the register urx_config, UART will filter out the data that cannot meet the width threshold. As shown in the figure below, when the data width is 4, setting cr_urx_deg_cnt to 4 can meet this condition. “Input” is the initial data and “output” is the filtered data.

Filtering logic process:

- “Tgl” is the exclusive OR result of input and output.
- “Deg_cnt” counts from 0, and the counting condition is that “tgl” is at the high level and “reached” is at the low level.
- If the count value of deg_cnt reaches the value set by cr_urx_deg_cnt, reached is high level.
- When “reached” is at a high level, “input” is output to “output” .
- Note: user-defined condition for deg_cnt: “tgl” is at a high level and “reached” is at a low level. In other cases, “deg_cnt” will be cleared to 0.

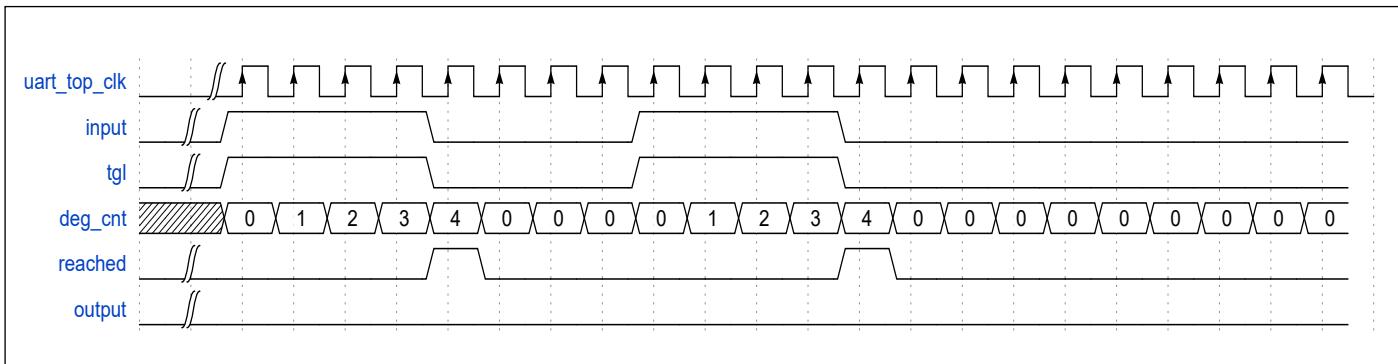

Fig. 16.5: UART Filter Waveform

16.3.6 Transmitter

The transmitter contains a 32-byte TX FIFO to store the data to be sent. When the transmission enable (Tx E) bit is set, the data stored in FIFO will be output from the TX pin. Software can transfer data into TX FIFO through DMA or APB bus. Software can check the status of transmitter by querying the remaining free space count value of TX FIFO through tx_fifo_cnt in the register uart_fifo_config_1.

FreeRun mode of transmitter:

- If the FreeRun mode is disabled, transmission will be terminated and an interrupt will be generated when the sent bytes reach the specified length. Before next transmission, you need to re-disable and enable the Tx E bit.
- If the FreeRun mode is enabled, the transmitter will send when there is data in the TX FIFO, and will not stop working because the sent bytes reach the specified length.

16.3.7 Receiver

The receiver contains a 32-byte RX FIFO to store the received data. Software can check the status of receiver by querying the available data count value of RX FIFO through rx_fifo_cnt in the register uart_fifo_config_1. The low 8 bits of the register URX_RTO_TIMER are used to set a receiving timeout threshold, which will trigger an interrupt when the receiver fails to receive data beyond the threshold. The cr_urx_deg_en and cr_urx_deg_cnt in the register urx_config are used to enable the deburring function and set the threshold, which control the filtering part before sampling by UART. UART will filter out the burrs whose width is lower than the threshold in the waveform and then

send it to sampling.

16.3.8 Automatic Baud Rate Detection

UART supports automatic baud rate detection, which includes the general mode and fixed character mode. The two modes will be enabled every time `cr_urx_abr_en` in the register `urx_config` is set.

Common mode

For any character data received, UART will count the number of clocks in the start bit width, which will then be written into the low 16 bits `sts_urx_abr_prd_start` in the register `STS_URX_ABR_PRD` and used to calculate the baud rate. So the correct baud rate can be obtained when the first received data bit is 1, such as ‘0x01’ under LSBFIRST.

Fixed character mode

In this mode, after UART counts the clocks in the start bit width, it will continue to count the clocks of the subsequent data bits and compare them with that of the start bit. If the fluctuation is within the allowable error range, the detection is passed, and otherwise, count values will be discarded. The allowable error can be set by configuring the `cr_urx_abr_pw_tol` bit in the register `urx_abr_pw_tol`, and the unit is the clock source of UART.

Thus, only when the fixed characters ‘0x55’ / ‘0xD5’ under LSBFIRST or the ‘0xAA’ / ‘0xAB’ under MSBFIRST are received, UART will write the clock count value in the start bit width into the high 16 bits `sts_urx_abr_prd_0x55` in the register `STS_URX_ABR_PRD`, as shown below:

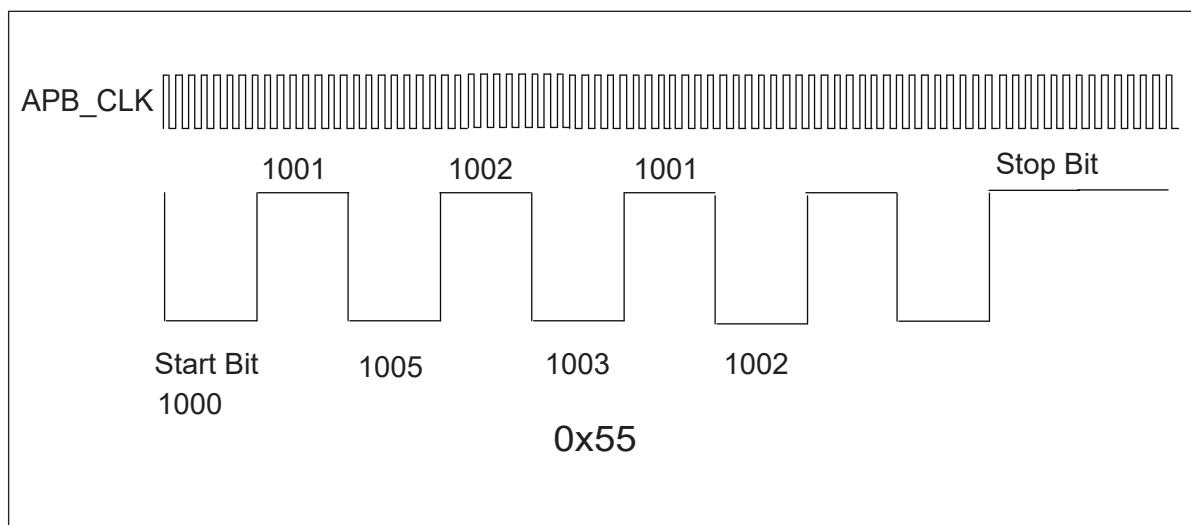

Fig. 16.6: Waveform of UART in fixed character mode

For an unknown baud rate, UART uses `UART_CLK` to count the width of the start bit and gets a count value of 1000, and the width of the second bit is 1001. If the width fluctuates for not more than four `UART_CLK` from the previous bit, UART will continue to count the third bit and get a count value of 1005. If the difference between the start bit and the third bit exceeds 4, the detection fails and the data will be discarded. UART compares the width of the first six data bits with that of the start bit in turn.

Formula for calculating the detected baud rate: baud rate = source clock/(16-bit detection value + 1)

16.3.9 Hardware Flow Control

UART supports hardware flow control in CTS/RTS mode to prevent data in FIFO from being lost due to too late processing. Hardware flow control connection is shown as follows:

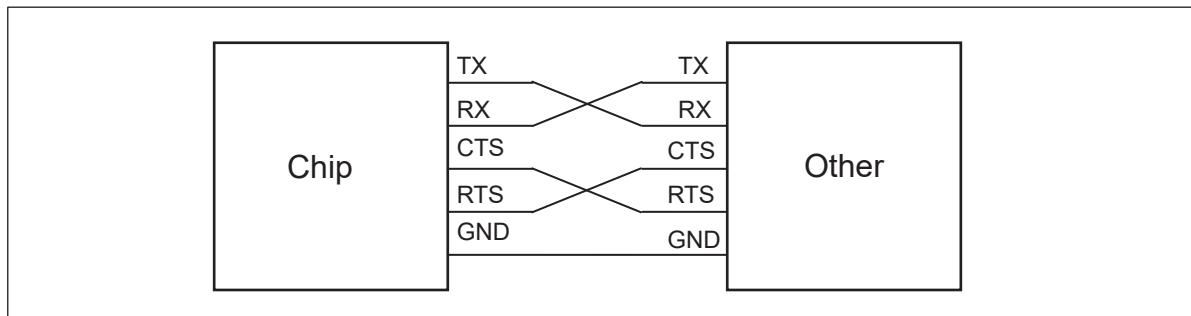

Fig. 16.7: UART hardware flow control

Require To Send (RTS) is an output signal, which indicates whether the chip is ready to receive data from the other side. This is valid at a low level denoting that the chip can receive data.

Clear To Send (CTS) is an input signal, which determines whether the chip can send data to the other side. This is valid at a low level denoting that the chip can send data to the other side.

When the hardware flow control function is enabled, the low level of chip's RTS indicates requesting the other side to send data, and the high level of that indicates informing the other side to stop sending data. When the chip detects that CTS goes high, TX will stop sending data, and continue sending until CTS goes low. If CTS goes high or low at any time during communication, it does not affect the continuity of data sent by TX, and the other side also can receive continuous data.

Two ways for hardware flow control of the transmitter:

- The cr_urx_rts_sw_mode in the register uart_sw_mode is 0: RTS goes high when cr_urx_en in the register urx_config is not turned on or the RX FIFO is almost full (one byte left).
- The cr_urx_rts_sw_mode in the register uart_sw_mode is 1: The level of RTS can be changed by configuring cr_urx_rts_sw_val in the register URX_SW_MODE.

16.3.10 DMA Transfer Mode

UART supports the DMA transfer mode. To enable this mode, you must set the thresholds of TX FIFO and RX FIFO through tx_fifo_th and rx_fifo_th in the register uart_fifo_config_1. When this mode is enabled, if tx_fifo_cnt in the uart_fifo_config_1 is greater than tx_fifo_th, the DMA TX request will be triggered. After DMA is configured, when receiving this request, DMA will transfer data from memory to TX FIFO as configured. If the rx_fifo_cnt in uart_fifo_config_1 is larger than rx_fifo_th, the DMA RX request will be triggered. After DMA is configured, when receiving this request, DMA will transfer the data in RX FIFO to the memory as configured. In the transmission mode, to ensure

correct data transfer by the DMA TX Channel, the Channel configuration must meet the condition that transferWidth multiplied by burstSize is less than or equal to the preset tx_fifo_th plus 1.

In the transmission mode, to ensure complete data transfer by the DMA RX Channel, the Channel configuration must meet the condition that transferWidth multiplied by burstSize is equal to the preset tx_fifo_th plus 1.

16.3.11 Support for LIN Bus

The protocol for the Local Interconnect Network (LIN) is based on the Volcano-Lite technology developed by the Volvo spin-out company—Volcano Communications Technology (VCT). LIN is a complementary protocol to CAN and SAE J1850, suitable for applications that have low requirement for time or require no precise fault tolerance (as LIN is not as reliable as CAN). LIN aims to be easy to use as a low-cost alternative to CAN. The vehicle parts where LIN can be used include window regulator, rearview mirror, wiper, and rain sensor.

UART supports the LIN bus mode, and a typical LIN data transfer is shown as follows.

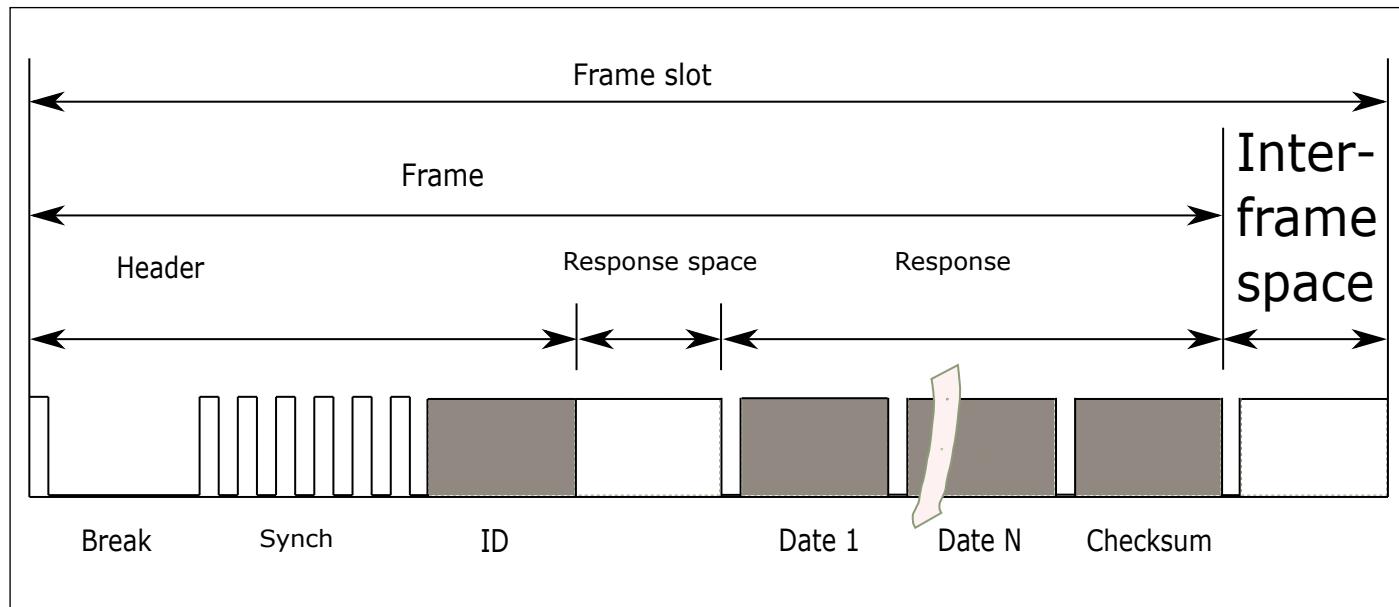

Fig. 16.8: A typical LIN frame

The LIN bus is under the master-slave mode, and data is always initiated by the master node. The frame (header) sent by the master node contains synchronization interval field, synchronization byte field, and identifier field.

The synchronization interval field indicates the start of the message, with at least 13 dominant bits (including the start bit). The synchronization interval ends with an “interval separator”, which contains at least one recessive bit.

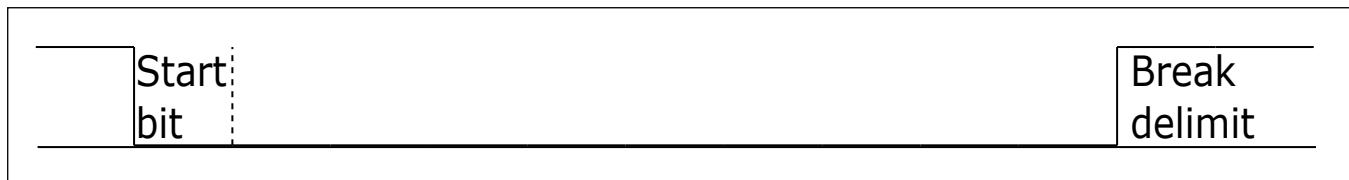

Fig. 16.9: Break Field of LIN

The length of the Break in the LIN frame can be set by `cr_utx_bit_cnt_b` in `utx_config`.

A synchronization byte field is sent to determine the time between two falling edges, to determine the transmission rate used by the master node. The bit pattern is 0x55 (01010101, maximum number of falling edges).

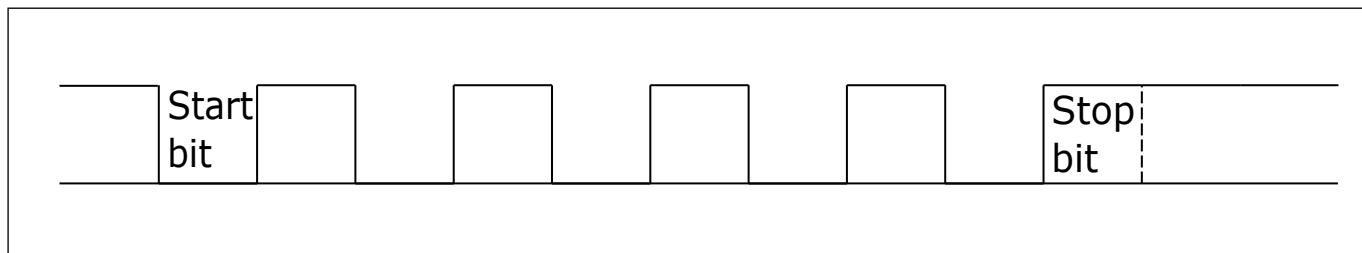

Fig. 16.10: Sync Field of LIN

The identifier field contains a 6-bit identifier and two parity check bits. The 6-bit identifier contains information about the sender and receiver, and the number of bytes required in the response. The parity check bit is calculated as follows: The check bit P0 is the result of logical OR operation among ID0, ID1, ID2, and ID4. The check bit P1 is the result of inversion after logical OR operation among ID1, ID3, ID4, and ID5.

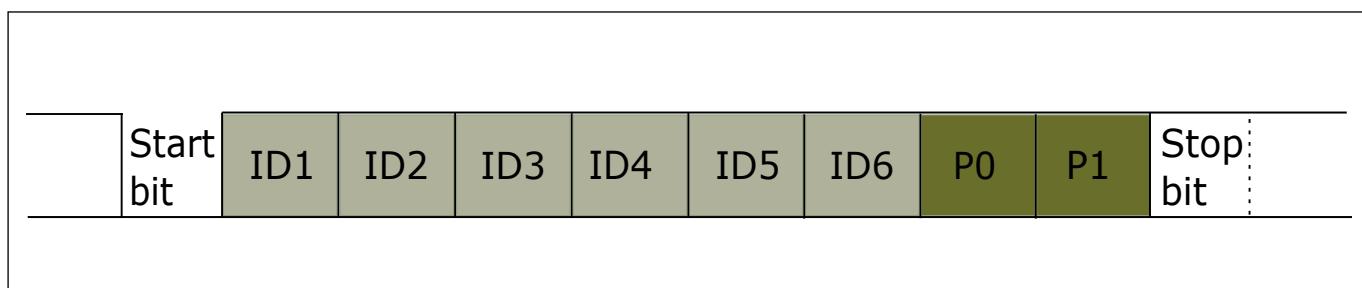

Fig. 16.11: ID Field of LIN

The slave node waits for the synchronization interval field, and then starts to synchronize between master and slave nodes through the synchronization byte field. Depending on the identifier sent by the master node, the slave node will receive, send or do not respond. The slave node that should send data sends the number of bytes requested by the master node, and then ends the transmission with a checksum field.

UART supports the LIN transfer mode. To enable this mode, you need to configure the `cr_utx_bit_cnt_b` by setting `cr_utx_lin_en` in the register `utx_config` so that the synchronization interval field consists of at least a 13-bit dominant level.

16.3.12 RS485 mode

UART supports the RS485 mode. After the cr_utx_rs485_en in the register UTX_RS485_CFG is set, UART can work in the RS485 mode. Then, UART can be connected to the RS485 bus through an external RS485 transceiver. In this mode, the RTS pin in the module performs the Dir function of transceiver. When UART has data to send, it will automatically control the RTS pin at a high level, so that the transceiver can send data to the bus. Contrarily, when UART has no data to send, it will automatically control the RTS at a low level, to keep the transceiver in the RX state.

UART supports the RS485 transfer mode. To enable this mode, you need to set cr_utx_rs485_pol and cr_utx_rs485_en in the register UTX_RS485_CFG.

16.3.13 UART Interrupt

UART supports the following interrupt control modes:

- TX end of transfer interrupt
- RX end interrupt
- TX FIFO request interrupt
- RX FIFO request interrupt
- RX timeout interrupt
- RX parity check error interrupt
- TX FIFO overflow interrupt
- RX FIFO overflow interrupt
- RX BCR interrupt
- LIN synchronization error interrupt
- Auto baud rate detection (universal mode) interrupt
- Auto baud rate detection (fixed characters mode) interrupt

16.3.14 TX/RX end of transfer interrupt

You can set a transfer length for TX and RX respectively by configuring the high 16 bits of the registers utx_config and urx_config. When the number of transferred bytes reaches this value, the corresponding TX/RX end of transfer interrupt will be triggered. While this interrupt is generated, TX stops working. To continue to use TX, you must re-initialize this module. Then, RX resumes to work. If the preset transfer length of TX is less than the data volume actually sent by TX, the other side can only receive the data equal to the transfer length, and the remaining data will be stored in TX FIFO. After this module is re-initialized, the data in TX FIFO can be sent out.

For example, if the TX/RX transfer length is 64 bytes, when the chip sends 63 bytes, no interrupt will be generated;

when it sends 1 byte again, a TX end interrupt will be generated as the number of transferred bytes reaches the preset transfer length of TX. After that, no data can be sent out again and all the data is stored in TX FIFO. When the other side sends 63 bytes to the chip, no interrupt will be generated; but when it sends 1 byte again, a RX end interrupt will be generated as the number of bytes received by the chip reaches the preset transfer length of RX. Then, if it sends 64 bytes to the chip again, UART can receive data and the FIFO data is not empty. When transferlen=15 is set, if TX sends 16-byte data, RX will receive 15-byte data only. The extra one byte is stored in TX FIFO, and the value of TX FIFO COUNT is 1 by default. After TX/RX is disabled and enabled again, the remaining data in TX FIFO will be sent out.

16.3.15 TX/RX FIFO request interrupt

A TX FIFO request interrupt will be generated when tx_fifo_cnt in uart_fifo_config_1 is greater than tx_fifo_th. When the condition is not met, the interrupt flag will be cleared automatically.

A RX FIFO request interrupt will be generated when rx_fifo_cnt in uart_fifo_config_1 is greater than rx_fifo_th. When the condition is not met, the interrupt flag will be cleared automatically.

TX/RX supports multiple rounds of transmission/receiving, instead of reaching the value set by tx_fifo_th/rx_fifo_th at a time.

For example, you can set tx_fifo_th/rx_fifo_th to 16 by configuring tx_fifo_th/rx_fifo_th in the register uart_fifo_config_1; enable the free run mode by setting cr_utx_frm_en in the register utx_config; enable the TX/RX FIFO interrupts by setting cr_utx_frdy_mask/cr_urx_frdy_mask in the register uart_int_mask to 0; enable TX/RX by setting cr_utx_en/cr_urx_en in the register utx_config/urx_config. TX FIFO interrupt: TX will always generate FIFO interrupts. After the chip sends 128 bytes, cr_utx_frdy_mask is set to 1 to mask this interrupt. To enable the TX FIFO interrupt again, you need to set cr_utx_frdy_mask to 0. RX FIFO interrupt: When the other side sends 15 bytes, no interrupt is generated and the value of rx_fifo_cnt is 15. When one byte is sent again, an interrupt will be generated as the preset value of rx_fifo_th is met. After a TX interrupt is generated, if the other side sends data again, the chip can receive the data.

16.3.16 RX timeout interrupt

The RX timeout interrupt will be triggered when the receiver fails to receive data beyond the timeout threshold. The timeout threshold is measured by Bit.

When the other side sends data to the chip, a timeout interrupt will be generated after the preset timeout threshold is reached. For example, you can enable the timeout interrupt by setting the cr_urx_rto_mask bit in the register uart_int_mask to 0, and data is received during the timeout interrupt. Through the printed RX buffer and the print log, you can confirm the timeout interrupt state and that correct data is received.

16.3.17 RX parity check error interrupt

The RX parity check error interrupt will be generated when a parity check error occurs. But it does not affect the RX, which still can correctly receive and analyze the data sent by the other side. When receiving data, RX takes the first 8 bits as data bits and ignores parity check bits, ensuring data consistency.

For example, you can enable parity check by setting cr_utx_prt_en/cr_urx_prt_en in the register utx_config/urx_config, and select the parity check type by setting cr_utx_prt_sel/cr_urx_prt_sel in the register utx_config/urx_config. When the other side sends data to the chip through odd/even parity check, the parity check of RX is disabled, but RX can receive correct data.

16.3.18 TX/RX FIFO overflow interrupt

If the TX/RX FIFO overflows or underflows, it will trigger the corresponding overflow interrupt. When the tx_fifo_clr and rx_fifo_clr bits in the FIFO clear bit register UART_FIFO_CONFIG_0 are set to 1, the corresponding FIFO will be cleared and the overflow interrupt flag will be cleared automatically. You can query the interrupt status through the register UART_INT_STS, and clear the interrupt by writing 1 to the corresponding bit in the register UART_INT_CLEAR.

16.3.19 RX BCR interrupt

A BCR interrupt will be generated when the data received by RX reaches the value set by cr_urx_bcr_value in the register urx_bcr_int_cfg.

The difference from RX END interrupt is that END interrupt is suitable for receiving data of known length, while BCR interrupt can be used to receive interrupts of unknown length. The trigger position of the END interrupt is controlled by cr_urx_len, and the counter will be cleared to 0 when an interrupt is triggered. The trigger position of BCR interrupt is controlled by cr_urx_bcr_value. When the interrupt is triggered, the counter will accumulate instead of being cleared to 0, but it can be cleared by software (cr_urx_bcr_clr). When the BCR interrupt is used together with the chained DMA, if you do not know how much data has been transferred by DMA, you can check it through “count” .

16.3.20 LIN synchronization error interrupt

When cr_utx_lin_en in utx_config is enabled, the LIN mode is enabled. Then, if the synchronization field of the LIN bus is not detected when data is received in this mode, the LIN synchronization error interrupt will be generated.

16.3.21 Auto baud rate detection (universal/fixed characters mode) interrupt

In the auto baud rate detection mode, when a baud rate is detected, the auto baud rate detection (universal/fixed characters mode) interrupt will be generated as configured.

17.1 Overview

Inter-Integrated Circuit (I2C) is a serial communication bus, which uses a multi-slave and multi-master architecture and is connected to low-speed peripherals. Each device has a unique address identifier and can be used as a transmitter or receiver. The address of each device connected to the bus can be set by software through a unique address and the existing master or slave relation. The master can work as a master transmitter or a master receiver. If two or more masters are initialized at the same time, data can be prevented from being damaged through conflict detection and arbitration during transmission.

BL808 has four I2C controller masters, whose slaveAddr, subAddr, and data to be transferred can be flexibly configured, to facilitate communication with slaves. With the FIFO of 2-word depth and interrupt function, it can be used with DMA to improve efficiency and supports flexible adjustment of clock frequency.

17.2 Features

- Master mode
- Multi-master mode and arbitration function
- Flexible adjustment of clock frequency
- Supports 10-bit address mode
- Supports DMA transfer mode

17.3 Functional Description

Table 17.1: I2C pin list

Name	Type	Description
I2Cx_SCL	Input/output	I2C serial clock signal
I2Cx_SDA	Input/output	I2C serial data signal

17.3.1 Start and stop conditions

All transmissions start with a START condition and end with a STOP condition. The START and STOP conditions are generally generated by the master. The bus is considered to be busy after the START condition and to be idle for a certain period of time after the STOP condition.

START condition: SDA produces a high-to-low level transition when SCL is high;

STOP condition: SDA produces a low-to-high level transition when SCL is high.

Waveform diagram:

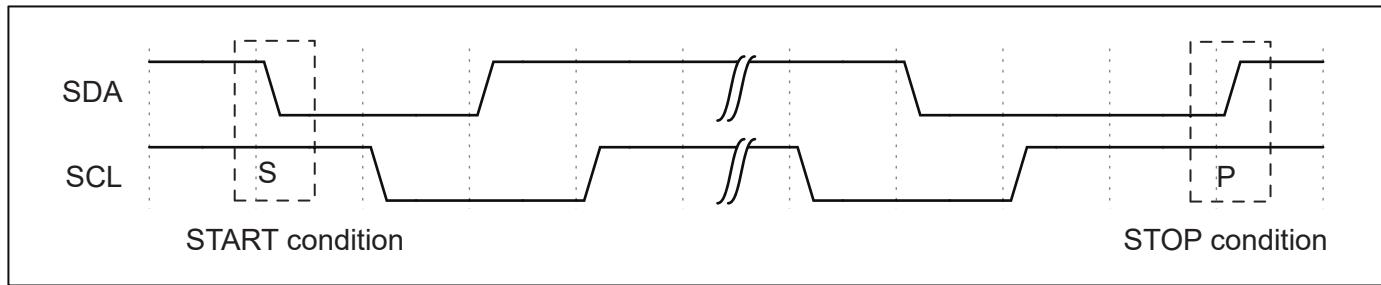

Fig. 17.1: Start and stop conditions of I2C

17.3.2 Data Transfer Format

7-bit address mode:

The first 8 bits transferred are addressing bytes, including a 7-bit slave address and a 1-bit direction bit. Sending or receiving data by the master is controlled by the 8th bit in the first byte sent by the master. If it is 0, it means that the data is sent by the master, while “1” indicates that data is received by the master, followed by the slave sending out an acknowledgement (ACK) bit. Upon data transfer completed, the master sends out a STOP signal, with waveform shown below:

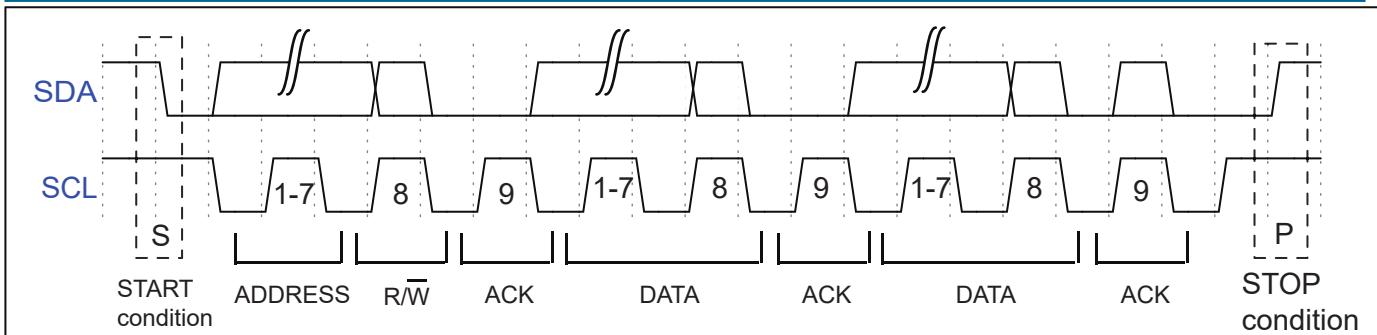

Fig. 17.2: I2C data transfer format

Master Transmit and Slave Receive Timing

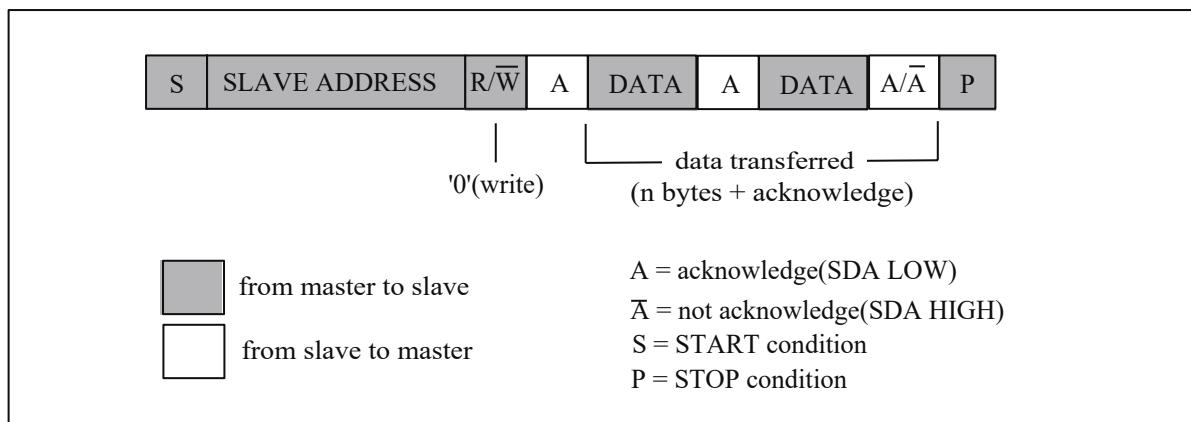

Fig. 17.3: Timing of master transmitter and slave receiver

Master Receive and Slave Transmit Timing

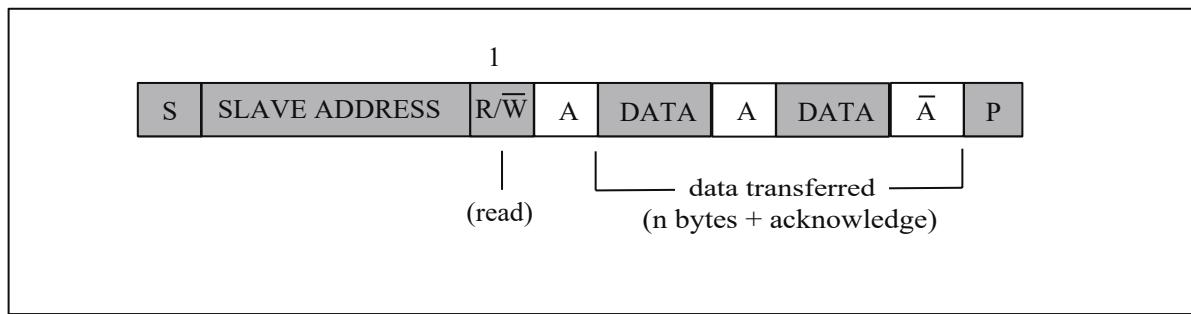

Fig. 17.4: Timing of master receiver and slave transmitter

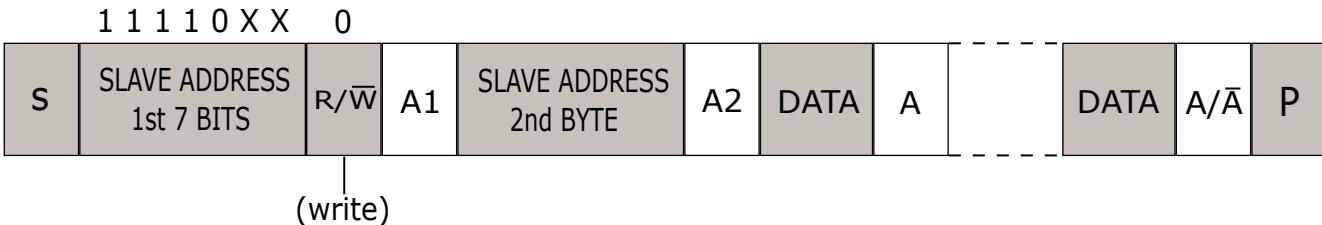

10-bit address mode: The cr_i2c_10b_addr_en in the register i2c_config must be set to 1 before use.

The 10-bit slave address consists of the two bytes after the START condition (S) or the repeated START condition (Sr). The first 7 bits of the first byte are 1111 0XX, where XX are the first two bits of MSB of the 10-bit address. The 8th bit of the first byte is the read/write bit that determines the transfer direction. Although there are 8 possible combinations

of 1111 XXX, only the four types of 1111 0XX can be used for 10-bit addressing, and the remaining four types of 1111 1XX are used for future I2C expansion.

The aforementioned read-write formats for 7-bit addressing all suit 10-bit addressing, as follows:

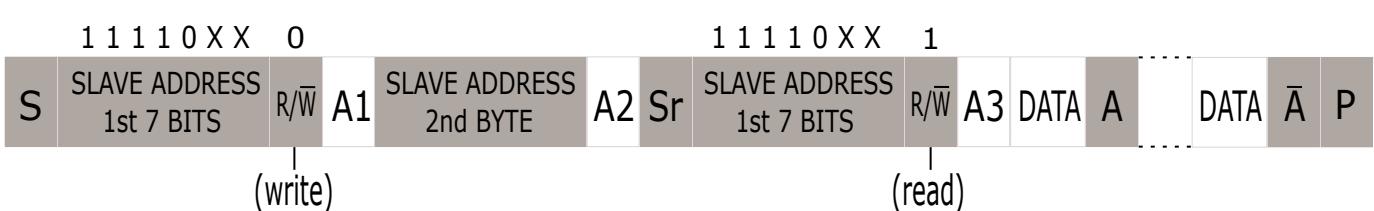

1. A master-transmitter sends data to a slave-receiver with a 10-bit slave address

A master-transmitter addresses a slave-receiver with a 10-bits address

The figure shows that the transfer direction is unchanged. When receiving the 10-bit address following the START condition, the slave compares the first byte (1111 0XX) of the slave address with its own address, and checks whether the eighth bit (read/write bit) is 0. It is possible that multiple devices all match and generate an acknowledgement (A1). Next, all the slaves start to match their own addresses with the 8 bits of the second byte (XXXX XXXX). At this time, only one slave matches and generates an acknowledgement (A2). The slave that is addressed by the master will remain in the addressed state until it receives a STOP condition or a repeated START condition, followed by a different slave address.

2. A master-receiver receives data from a slave-transmitter (10-bit slave address)

A master-receiver addresses a slave-transmitter with a 10-bits address

The transfer direction will change after the second read/write bit. Before the second acknowledgement A2, the process is the same as that of the master-transmitter addressing the slave-receiver. After the repeated START condition (Sr), the matched slave will remain in the addressed state. This slave will check whether the first 7 bits of the first byte after Sr are correct, and then test whether the 8th bit is 1 (read). If this also matches, the slave considers that it is addressed as a transmitter and generates an acknowledgement (A3). The slave-transmitter will remain in the addressed state until it receives the STOP condition (P) or the repeated START condition (Sr) followed by a different slave address. Then, under Sr, all the slaves will compare their addresses with 11110XX and test the eighth bit (read/write bit). However, they will not be addressed, because for 10-bit devices, the read/write bit is 1, or for 7-bit devices, the slave

addresses of 1111 0XX do not match.

17.3.3 Arbitration

When there are multiple masters on I2C bus, it may happen that multiple masters start data transfer at the same time. At this time, the arbitration mechanism will decide which master has the right to transfer data, while other masters have to give up the control of the bus and wait until the bus is idle before transferring data again.

During data transfer, all masters must check whether the SDA is consistent with the data they want to send when SCL stays high. When the SDA level is different from the expected one, it means that other masters are transferring data at the same time. The masters with different SDA levels will lose the arbitration and other masters will complete the data transfer.

The waveform of two masters transferring data and initiating the arbitration mechanism at the same time is as follows:

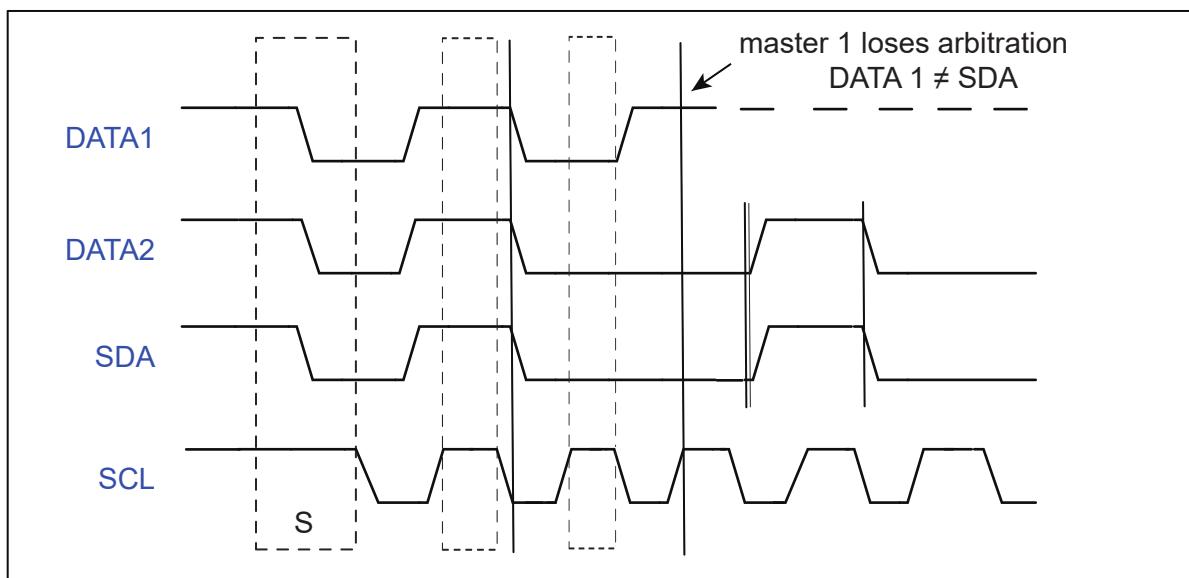

Fig. 17.5: Waveform of simultaneous data transfer

17.4 I2C Clock Setting

I2C clock can be derived from bclk (bus clock) and xclk, and frequency division can be done on this basis. The register i2c_prd_data can divide the clock of the data segment. The I2C module divides data transfer into 4 stages. Each stage is controlled by a single byte in the register, and the number of samples of each stage can be set. The 4 numbers jointly determine the division factor of i2c clock.

For example, bclk is 32M now, and the default value of the register i2c_prd_data is 0x0f0f0f0f without configuration, so I2C's clock frequency is $32M / ((15 + 1) * 4) = 500K$. Similarly, registers i2c_prd_start and i2c_prd_stop will divide the clock of the start and stop bits, respectively.

17.5 I2C Configuration Flow

17.5.1 Configuration Items

- Read/write flag bit
- Slave address
- Slave register address
- Slave register address length
- Data (TX: configure the sent data; RX: store the received data)
- Data length
- Enable signal

17.5.2 Read/Write Flag Bit

I2C supports TX and RX working statuses. The cr_i2c_pkt_dir in the register i2c_config represents the TX/RX status, “0” for TX status and “1” for RX status.

17.5.3 Slave Address

Each slave connected to I2C will have a unique device address, which is usually 7 bits long. This address will be written into the cr_i2c_slv_addr in the register i2c_config. I2C will automatically shift to the left by 1 bit before sending the address, and the TX/RX direction bit will be added to the LSB.

17.5.4 Slave Register Address

The slave register address represents the register address where I2C needs to read and write a slave register. The slave register address is written to the register i2c_sub_addr, and the cr_i2c_sub_addr_en in the register i2c_config must be set to 1. If cr_i2c_sub_addr_en in the register i2c_config is set to 0, the I2C master will skip the slave register address field when sending.

17.5.5 Slave Register Address Length

The slave register address length is subtracted by 1 and then written to cr_i2c_sub_addr_bc in the register i2c_config.

17.5.6 Data

It refers to the data that needs to be sent to or received from the slave. When sending data, I2C must write the data (in word) into the register i2c_fifo_wdata. When receiving data, I2C must read out the data (in word) from the register i2c_fifo_rdata.

17.5.7 Data Length

The data length is subtracted by 1 and then written to cr_i2c_pkt_len in the register i2c_config.

17.5.8 Enable Signal

After the above items are configured, when cr_i2c_m_en in the enable signal register i2c_config is set to 1, the I2C sending process will be started automatically.

When the read/write flag bit is configured as 0, I2C sends data and the master's transmission flow is as follows:

1. Start bit
2. (The slave address shifts to the left by 1 bit + 0) + ACK
3. Slave register address + ACK
4. 1-byte data + ACK
5. 1-byte data + ACK
6. Stop bit

When the read/write flag bit is configured as 1, I2C receives data and the master's transmission flow is as follows:

1. Start bit
2. (The slave address shifts to the left by 1 bit + 0) + ACK
3. Slave register address + ACK
4. Start bit
5. (The slave address shifts to the left by 1 bit + 1) + ACK
6. 1-byte data + ACK
7. 1-byte data + ACK
8. Stop bit

17.6 FIFO Management

I2C FIFO has a 2-word depth, and I2C includes RX FIFO and TX FIFO. The rx_fifo_cnt in the register i2c_fifo_config_1 represents how much data (in word) in RX FIFO needs to be read. The tx_fifo_cnt in the register i2c_fifo_config_1 represents how much free space (in word) in TX FIFO for writing.

I2C FIFO status:

- RX FIFO underflow: When the data in RX FIFO is completely read out or empty, if I2C continues to read data from RX FIFO, the rx_fifo_underflow in the register i2c_fifo_config_0 will be set to 1;
- RX FIFO overflow: When I2C receives data until the two words of RX FIFO are filled, without reading RX FIFO, if I2C receives data again, the rx_fifo_overflow in the register i2c_fifo_config_0 will be set to 1;
- TX FIFO underflow: When the data size filled into TX FIFO does not meet the configured I2C data length: cr_i2c_pkt_len in i2c_config, and no new data is filled into TX FIFO, the tx_fifo_underflow in the register i2c_fifo_config_0 will be set to 1;
- TX FIFO overflow: After the two words of TX FIFO are filled, before the data in TX FIFO is sent out, if data is filled into TX FIFO again, the tx_fifo_overflow in the register i2c_fifo_config_0 will be set to 1.

17.7 Use with DMA

I2C can send and receive data through DMA. Setting i2c_dma_tx_en in the register i2c_fifo_config_0 to 1 will enable the DMA TX mode. After the channel for I2C is allocated, DMA will transfer data from memory to the i2c_fifo_wdata register. Setting i2c_dma_rx_en in the register i2c_fifo_config_0 to 1 will enable the DMA RX mode. After the channel for I2C is allocated, DMA will transfer the data in the register i2c_fifo_rdata to memory. When I2C is used with DMA, DMA will automatically transfer data, so it is unnecessary for CPU to write data into I2C TX FIFO or read data from I2C RX FIFO.

17.7.1 DMA Sending Flow

1. Set read/write flag bit to 0
2. Set slave address
3. Set slave register address
4. Set slave register address length
5. Data Length
6. Set enable signal register to 1
7. Configure DMA transfer size
8. Configure the transfer width of DMA source address
9. Configure the transfer width of DMA destination address (when I2C is used with DMA, the transfer width of desti-

nation address must be set to 32 bits, which is word-aligned)

10. Configure the DMA source address as the memory address for storing sent data
11. Configure the DMA destination address to I2C TX FIFO address, i2c_fifo_wdata
12. Enable DMA

17.7.2 DMA Receiving Flow

1. Set read/write flag bit to 1
2. Set slave address
3. Set slave register address
4. Set slave register address length
5. Data Length
6. Set enable signal register to 1
7. Configure DMA transfer size
8. Configure the transfer width of DMA source address (when I2C is used with DMA, the transfer width of source address must be set to 32 bits, which is word-aligned)
9. Configure the transfer width of DMA destination address
10. Configure the DMA source address to I2C RX FIFO address, i2c_fifo_rdata
11. Configure the DMA destination address as the memory address for storing received data
12. Enable DMA

17.8 Interrupt

I2C includes the following interrupts:

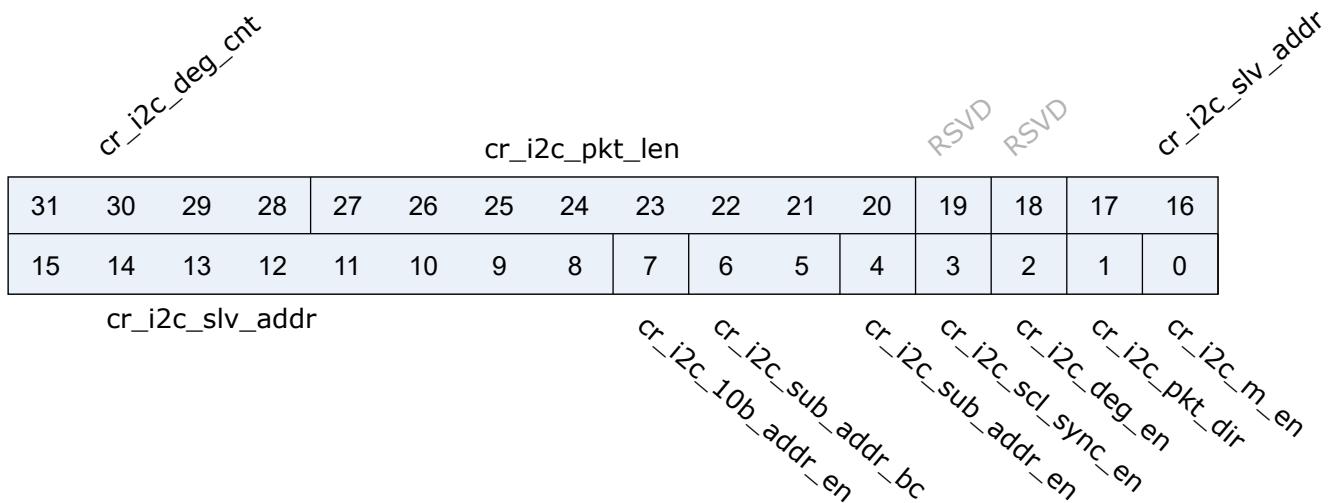

- I2C_TRANS_END_INT: I2C end of transfer interrupt
- I2C_TX_FIFO_READY_INT: The interrupt is triggered when I2C TX FIFO has free space for padding
- I2C_RX_FIFO_READY_INT: The interrupt is triggered when I2C RX FIFO receives data
- I2C_NACK_RECV_INT: The interrupt is triggered when I2C detects the NACK state
- I2C_ARB_LOST_INT: I2C arbitration lost interrupt
- I2C_FIFO_ERR_INT: I2C FIFO ERROR interrupt

PWM

18.1 Overview

Pulse Width Modulation (PWM), an efficient technique that uses the digital signal of microprocessor to control the analog circuit, is widely used in fields like measurement, communication, and power control and conversion.

18.2 Features

- Two PWM signals are generated, each containing 4-channel PWM signal outputs, with 2 pairs of complementary PWM per channel
- There are optional three clock sources (bus clock<bclk>, crystal oscillator clock<xtal_ck>, and slow clock<32k>), with 16-bit clock divider
- Each PWM can be independently set to different cycles
- Each PWM channel has double threshold setting, allowing different duty ratios and phases, with more flexible pulse
- Each PWM channel has independent dead time setting
- Different active levels can be set for each PWM output pin
- Each PWM has an independent linked switch to connect/disconnect with the internal counter, and you can set the default output level when disconnected
- The software and external brake signals can set the PWM output level to a preset state
- Up to 9 trigger sources for triggering ADC conversion
- Interrupts will be generated when these events occur: counter overflow, threshold comparison and matching, brake signal generation, and PWM cycles reaching the set value.

18.3 Functional Description

18.3.1 Clock and Frequency Divider

Each PWM counter has three optional clock sources:

1. bclk—bus clock of chip
2. XTAL—external crystal oscillator clock
3. f32k—RTC clock of system

Each counter has its own 16-bit frequency divider, which can divide the selected clock through APB. The PWM counter will take the divided clock as the counting cycle unit, and add one every time a counting cycle ends.

18.3.2 Active Level

Different application scenarios require different active level states, some being active at low level and others being active at high level. The active level of each PWM output can be set independently.

When the `<pwm_chy_ppl>` bit in the register `pwm_mcx_config1` is set to 1, it means that the forward channel of channel y ($y = 0, 1, 2, 3$) of `pwmx` ($x = 0, 1$) is set to be active at high level. That is, when the PWM module outputs logical ‘1’, its corresponding pin outputs high level, and when it outputs logical ‘0’, that outputs low level. When `<pwm_chy_ppl>` is set to 0, it means that the same is set to be active at low level. That is, when the PWM module outputs logical ‘1’, its corresponding pin outputs low level, and when it outputs logical ‘0’, that outputs high level. The setting bit of the complementary channel is `<pwm_chy_npl>`, and its setting rule is the same as that of the forward channel.

18.3.3 Principle of Pulse Generation

When the `<pwm_chy_pen>` bit in the register `pwm_mcx_config1` is set to 0, it means that the forward channel of channel y ($y = 0, 1, 2, 3$) of `pwmx` ($x = 0, 1$) is set to a determined logic state, and then the state is determined by the `<pwm_chy_psi>` bit. When `<pwm_chy_psi>` is 0, the corresponding forward channel pin outputs logical ‘0’, and when the same is 1, that outputs logical ‘1’. The actual output level must be jointly determined with `<pwm_chy_ppl>`. The setting bit of the complementary channel is `<pwm_chy_nen>`, and its setting rule is the same as that of the forward channel.

When the `<pwm_chy_pen>` (`<pwm_chy_nen>`) bit in the register `pwm_mcx_config1` is set to 1, the forward (complementary) channel output of channel y ($y = 0, 1, 2, 3$) of `pwmx` ($x = 0, 1$) is determined by comparing the internal counter with the two thresholds. If the counter value is between the two thresholds, the forward channel outputs logical ‘1’, while the complementary one outputs logical ‘0’. If the counter value is beyond the two thresholds, the forward channel outputs logical ‘0’, while the complementary one outputs logical ‘1’. The waveform is shown as follows.

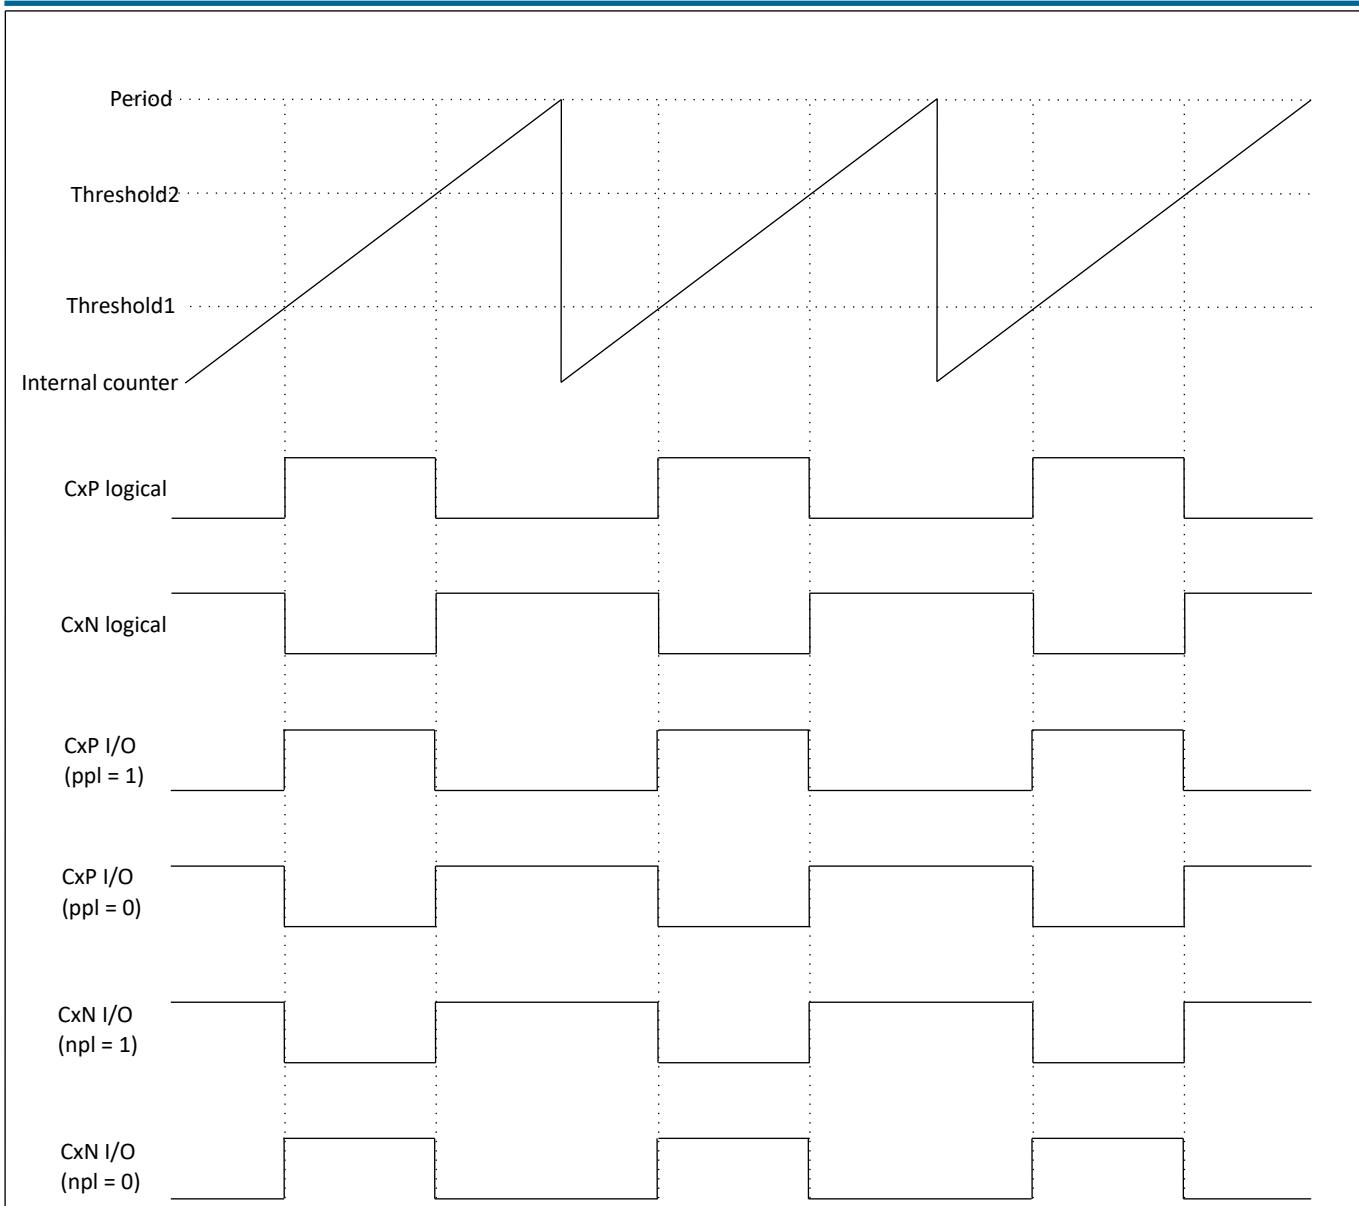

Fig. 18.1: Waveform of PWM in different configurations

18.3.4 Brake

When the brake function is used and the brake signal is generated, the level of the PWM output will be changed to a preset state, which is determined by the `<pwm_chy_pbs>` and `<pwm_chy_nbs>` ($y = 0, 1, 2, 3$) bits in the register `pwm_mcx_config1` ($x = 0, 1$). When the bits are set to 1, PWM outputs logical ‘1’ after the brake signal is generated. When the same is set to 0, PWM outputs logical ‘0’ after the brake signal is generated.

Brake signals include external brake and software brake. When the `<pwm_sw_break_en>` in `pwm_mcx_config0` ($x = 0, 1$) is 1, the internal brake signal will be generated. When this bit is 0, the brake state will be exited and PWM will resume to its previous operation mode. When the `<pwm_ext_break_en>` bit is 1, the external brake function is enabled. If the external brake pin state matches the value set by `<pwm_ext_break_pl>`, a brake signal will be generated. If that state is opposite to the value set by `<pwm_ext_break_pl>`, PWM will exit the brake state. It should

be noted that only PWM0 supports external brake, and PWM1 cannot do that.

If the brake interrupt is enabled, the interrupt will be triggered when the external brake signal is generated. Software brake will not trigger an interrupt.

18.3.5 Dead Zone

Different dead time can be set for each PWM channel independently. When the value of dead time is not 0, the forward channel of PWM will delay the generation of jump level when it matches the threshold 1, and immediately change the level state when it matches the threshold 2. The complementary channel of PWM will change the level state immediately when it matches the threshold 1, and delay the generation of jump level when it matches the threshold 2. The length of dead zone is set by the register `pwm_mcx_dead_time`.

18.3.6 Cycle and Duty Ratio Calculation

The PWM cycle is determined the clock division factor and the clock duration cycle. The clock division factor is set by the register `PWMx_CLK_DIV[15:0](x: 0~1)` and is used to divide the source clock of PWM. The clock duration cycle is set by the register `PWMx_PERIOD[15:0](x: 0~1)` and is used to set how many divided clock cycles a PWM cycle consists of. That is, $\text{PWM cycle} = \text{PWM source clock}/\text{PWMx_CLK_DIV[15:0]}/\text{PWMx_PERIOD[15:0]}$.

18.3.7 PWM Interrupt

For each PWM, the cycle count value can be set by the high 16 bits of the register `pwm_mcx_period`. When the number of PWM cycles reaches this value, the PWM interrupt will be generated.

When the PWM count value reaches the number of cycles or it matches the threshold, the PWM interrupt will be generated.

A PWM interrupt will be generated when an external brake signal is generated.

18.3.8 ADC Linkage

When the counter matches the threshold or the count value reaches the number of cycles, it will generate the signal that internally triggers ADC startup conversion. It should be noted that only PWM0 can trigger such conversion, while PWM1 cannot do that. The specific trigger source is set by the `<pwm_adc_trg_src>` bit in the register `pwm_mcx_config0`. This feature is commonly used in timing sampling. The following is an example.

Application scenario: In BLDC application, there is such a requirement that the current flowing through the coil shall be detected while the motor speed is controlled by PWM. In a PWM cycle, after PWM controls the power device to turn on, the current becomes stable after a certain period of time. Then, it is necessary to sample the current value, which means that there is a strict phase difference between the time point of triggering ADC conversion and PWM. For example, if the channel 0 of PWM is used to drive one of the phases of the motor, and a 10 KHz square wave with a duty ratio of 20% needs to be generated, and ADC sampling needs to be performed at the middle time point of the high level of the square wave, then the PWM cycle is 100us. When the clock source is 1 MHz, the cycle count value is 100, and the two thresholds of channel 1 can be set to 0 and 20 respectively. At this time, the counter is between

0 and 20, and PWM outputs a high level, and otherwise it outputs a low level. When the threshold L of channel 2 is set to 10 and the `pwm_adc_trg_src` in the register `pwm_mc0_config0` is set to 4, `pwm_ch2l_int` can trigger ADC conversion. When the counter counts to 10, ADC will start sampling conversion at the middle time point of the high level generated by channel 1. This ensures that each sampling can meet the exact time requirement without CPU intervention, thus improving the performance.

19.1 Overview

Two 32-bit counters are built in the chip, and each can independently control and configure its parameters and clock frequency.

There is one watchdog counter in the chip. Unpredictable software or hardware behavior may cause the application to malfunction, and the watchdog timer can help recover the system. If the current stage exceeds the preset time, but the watchdog is not reset or turned off, the interrupt or system reset can be triggered as configured.

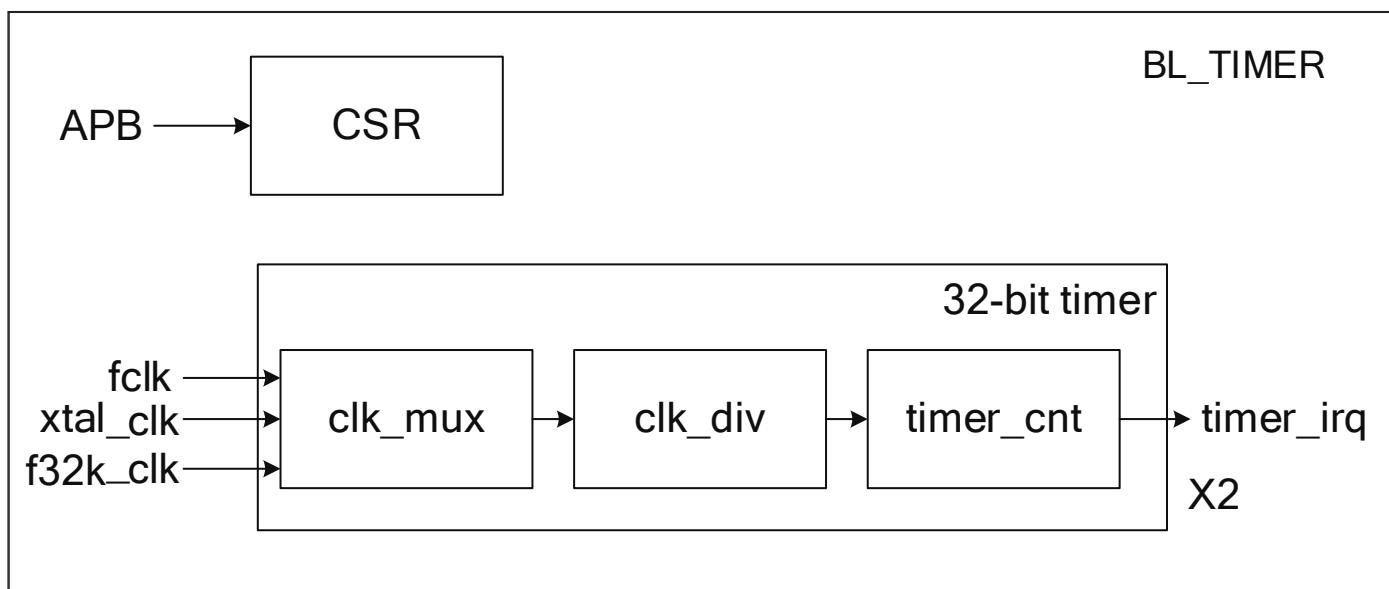

Fig. 19.1: Block diagram of timer

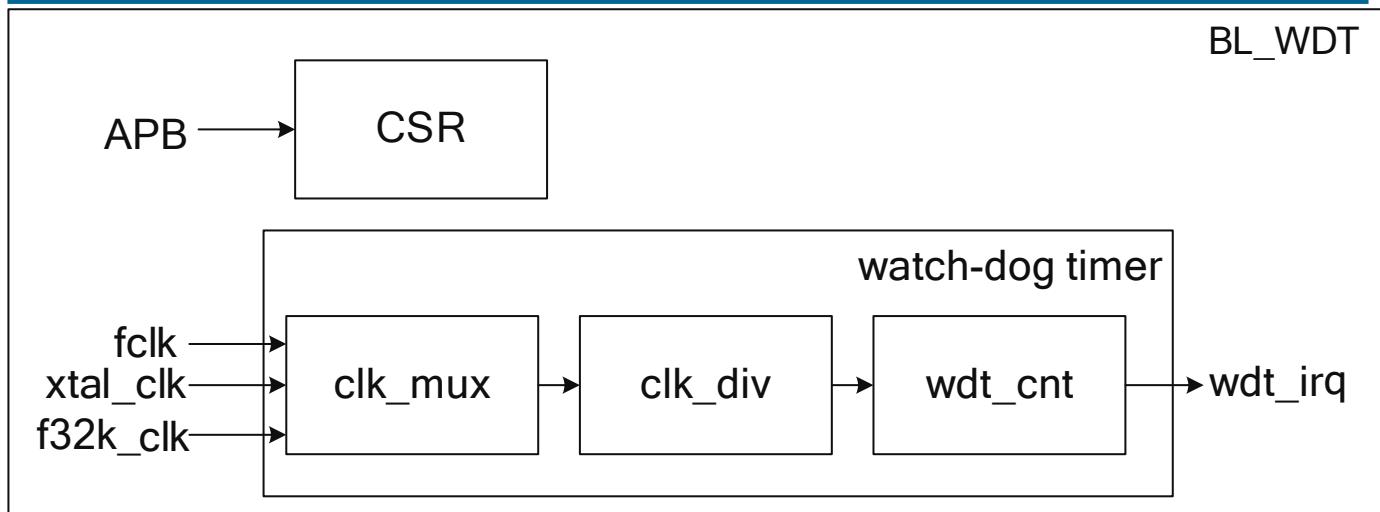

Fig. 19.2: Block diagram of watchdog timer

19.2 Features

- Multiple clock sources, up to 80M clock supported
- Bit clock divider with a division factor of 1-256
- Two 32-bit timers
- Each timer has three alarm value settings, and the alarm when each set of alarm values overflows can be independently set.
- Supports Free Run mode and Pre_load mode
- With 16-bit watchdog timer
- Supports write password protection to prevent system error caused by wrong settings
- Supports two watchdog overflow modes: interrupt or reset
- Supports measuring the pulse width of external GPIO

19.3 Functional Description

There are 5 types of watchdog timer clocks:

- Bclk-bus clock
- 32K-32K clock
- 1K-1K clock
- Xtal-external crystal oscillator
- GPIO-external GPIO

It is configured by cs_wdt in the register TCCR.

There are 5 types of timer clock sources:

- Bclk-bus clock
- 32K-32K clock
- 1K-1K clock(32K frequency division)
- Xtal-external crystal oscillator
- GPIO-external GPIO

It is configured by cs_2 and cs_3 in the register TCCR.

Each counter has its own 8-bit frequency divider, which can divide the clock by 1-256. Specifically, when it is set to 0, it means no frequency division. When it is set to 1, it will divide the clock by 2, and so on. The maximum division factor is 256, and the counter will take the divided clock as the counting cycle unit.

It is configured by tcdr2, tcdrl3, and wcdrl in the register TCDR.

19.3.1 Working Principle of General Purpose Timer

Each general purpose timer contains three comparators, one counter, and one PreLoad register. When the clock source is set and the timer is started, the counter starts to count up cumulatively. When the value of counter is equal to that of the comparator, the comparison flag is set and a comparison interrupt can be generated.

You can configure the value of TMR2 comparator 0 by setting tclr2_0, that of TMR2 comparator 1 by setting tclr2_1, and that of TMR2 comparator 2 by setting tclr2_2 in the register TICR2. The tplvr2 in the register TPLVR2 sets the TMR2 preload value.

You can configure the value of TMR3 comparator 0 by setting tclr3_0, that of TMR3 comparator 1 by setting tclr3_1, and that of TMR3 comparator 2 by setting tclr3_2 in the register TICR3. The tplvr3 in the register TPLVR3 sets the TMR3 preload value.

The counter's initial value depends on the timing mode. In the FreeRun mode, this initial value is 0, and then the counter counts up cumulatively. After reaching the maximum value, it starts counting again from 0.

In the PreLoad mode, this initial value is the value of the PreLoad register, and then counts up cumulatively. When the PreLoad condition is met, the counter's value is set to the value of the PreLoad register, and then the counter starts counting up cumulatively again. In the counting process of the timer's counter, once the counter's value is consistent with one comparison value of three comparators, the comparison flag of the comparator will be set, and the corresponding comparison interrupt can be generated.

You can configure the counting mode of TMR2 by setting timer2_mode and that of TMR3 by setting timer3_mode in the register TCMR.

If the value of the PreLoad register is 10, and the values of comparators 0, 1, and 2 are 13, 16, and 19 respectively,

the working sequence of the timer in the PreLoad mode is as follows:

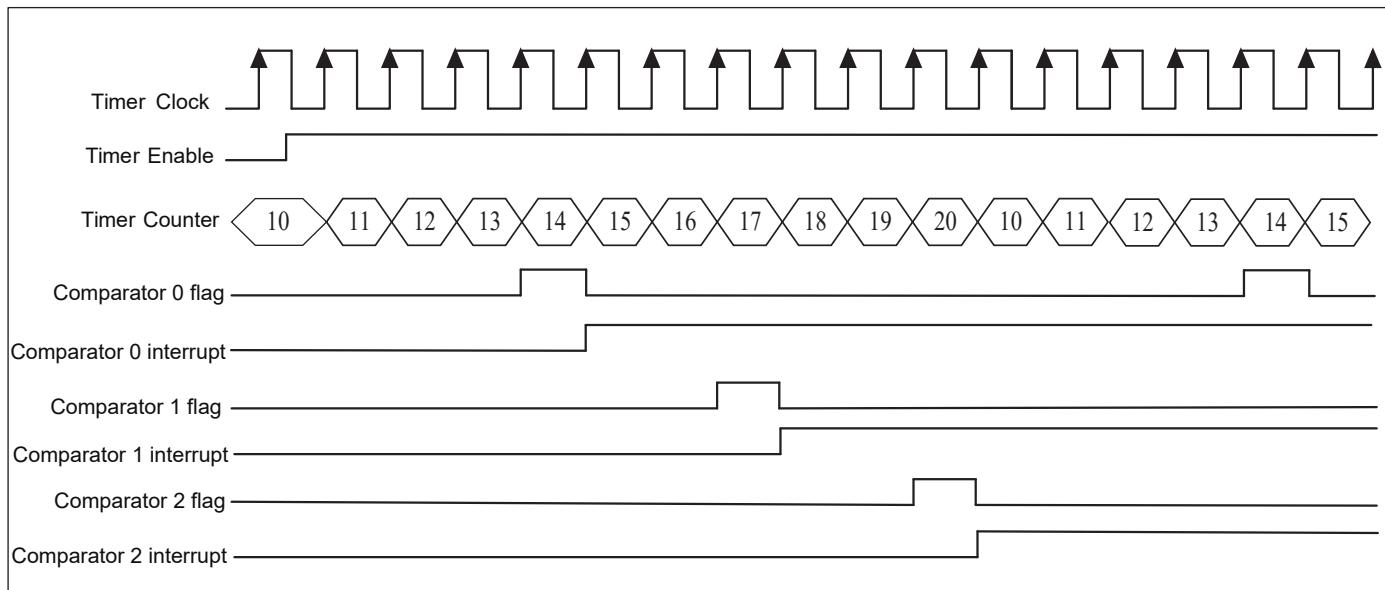

Fig. 19.3: Working sequence of timer in preLoad mode

In FreeRun mode, the working timing of the timer is basically the same as that of PreLoad, except that the counter will accumulate from 0 to the maximum value, and the mechanism of comparison flag and comparison interrupt generated during this period is the same as that of FreeRun mode.

TMR2 can use the internal clock source to calculate the pulse width of the external gpio. This function is enabled by setting `timer2_gpio_en` in the register GPIO. By setting the `timer2_gpio_inv` bit, it is judged whether the high level or low level of the external gpio is obtained. If the bit is 0, it means high level; if the bit is 1, it means Low level; in addition, the external gpio function needs to be set to the `gpio_tmr_clk` function. By configuring the `gpio_tmr_clk_sel[13:12]` bits in the register `dig_clk_cfg2` in the GLB module; at the same time, you need to configure a bit in the register `dig_clk_cfg2[11:8]` to 0, which needs to be used in conjunction with `gpio_tmr_clk_sel`. details as follows:

- If `gpio_tmr_clk_sel[13:12]` is configured as 0, then `chip_clk_out_0_en` in register `dig_clk_cfg2` is set to 0
- If `gpio_tmr_clk_sel[13:12]` is configured as 1, then `chip_clk_out_1_en` in register `dig_clk_cfg2` is set to 0
- If `gpio_tmr_clk_sel[13:12]` is configured as 2, then `chip_clk_out_2_en` in register `dig_clk_cfg2` is set to 0
- If `gpio_tmr_clk_sel[13:12]` is configured as 3, then `chip_clk_out_3_en` in register `dig_clk_cfg2` is set to 0

After the configuration is complete, enable the timer. When the `gpio_lat_ok` in the register GPIO is set to 1, the values of the register `GPIO_LAT2` and the register `GPIO_LAT1` are obtained. The calculation method of the pulse width of the external gpio: $(\text{GPIO_LAT2} - \text{GPIO_LAT1}) * \text{the width of 1 cycle of the internal clock source of the timer}$.

For example: the internal clock source of the timer is 80M, the frequency of the external gpio is 2M, and the duty ratio is 1:1. Write 1 to the `timer2_gpio_inv` bit to calculate the width of the low level of the external gpio. After the above configuration is completed, the difference between the register `GPIO_LAT2` and the register `GPIO_LAT1` is 20, then the low level width of the external gpio is: $20 * (1 / 80000000) = 1 / 4000000$; Write 0 to the `timer2_gpio_inv` bit,

which means to calculate the width of the high level of the external gpio. After the above configuration is completed, the difference between the register GPIO_LAT2 and the register GPIO_LAT1 is 20, then the high level width of the external gpio is: $20 * (1 / 80000000) = 1 / 4000000$;

19.3.2 Working Principle of Watchdog Timer

The watchdog timer integrates a counter and a comparator. The counter counts up from 0 cumulatively. If the counter is reset, it counts up again from 0. When the value of counter is equal to that of the comparator, it can generate a comparison interrupt signal or a system reset signal. Users may use one of them as required. The watchdog counter will add 1 to each counting cycle unit, and the software can reset this counter to zero through APB at any time.

The wmr in the register WMR sets the comparison value.

If the comparator value is 6, the working sequence of Watchdog is shown as follows:

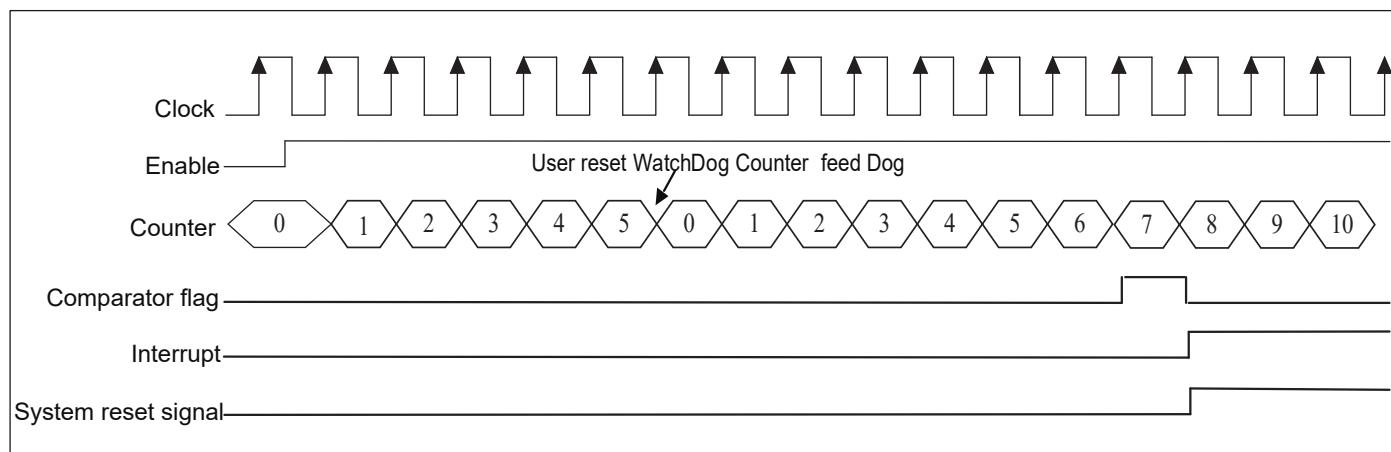

Fig. 19.4: Working sequence of watchdog

19.3.3 Alarm Setting

Each set of counter has three comparison values to provide software settings, and it can set whether each comparison value triggers an alarm interrupt. When the counter's value matches the comparison value and an alarm will be given, the counter will notify the processor through interrupts.

Through APB, the software can read whether there is an alarm at present and which comparison value triggers the alarm interrupt. When the alarm interrupt is cleared, the alarm state will also be cleared synchronously.

19.3.4 Watchdog Alarm

Each counter can be configured with one comparison value. When the watchdog counter is too late to be reset to zero due to a system error, which causes the watchdog counter to exceed the comparison value, it will trigger the watchdog alarm. There are two alarm modes. One is to notify the software to process it by generating an interrupt. The other one is to perform watchdog reset. When the watchdog reset is triggered, it will notify the system's reset controller and prepare for system reset. When everything is ready, the watchdog reset will be performed. It is worth noting that the software can read WSR register through APB to know whether watchdog reset has occurred.

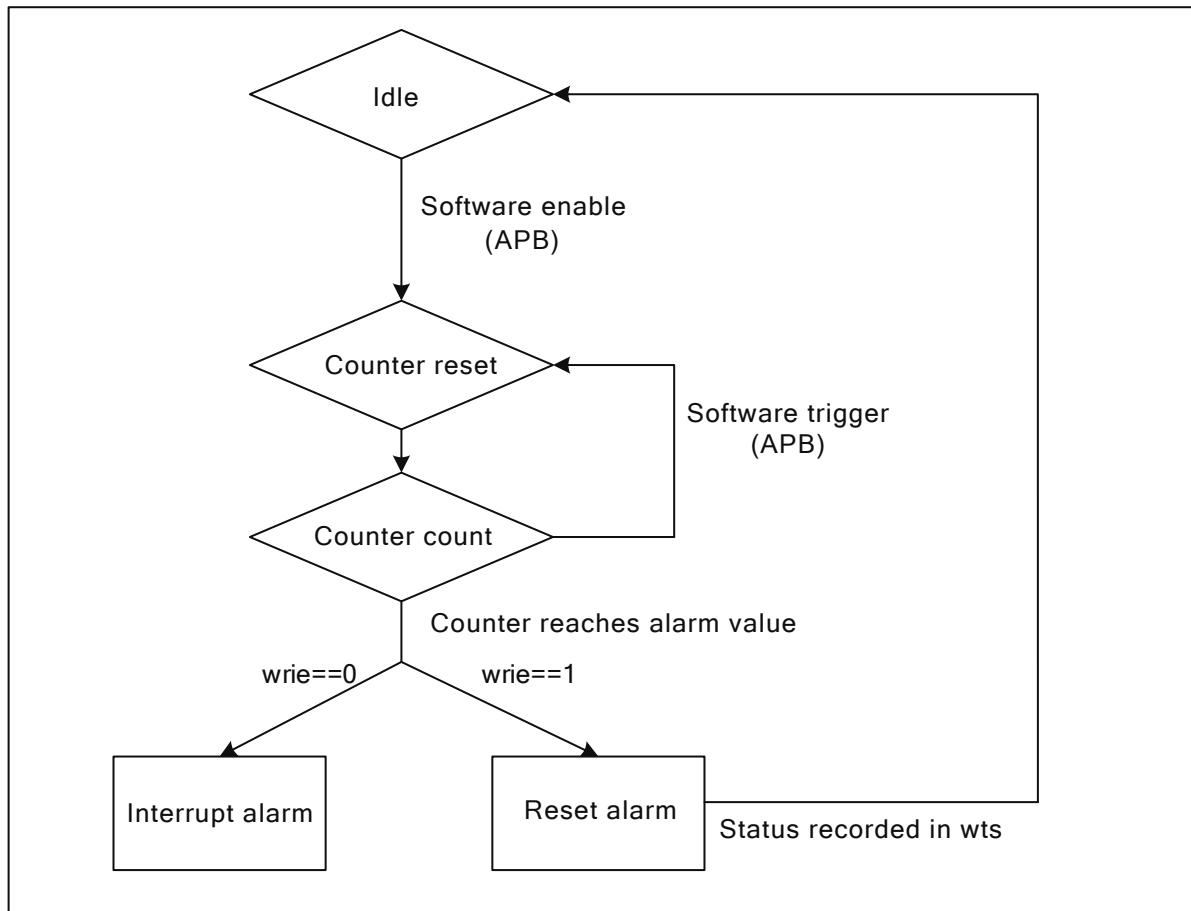

Fig. 19.5: Watchdog alarm mechanism

20.1 Overview

InterIC Sound (I2S), also Integrated Interchip Sound (IIS), is a digital audio transmission specification defined by Philips in 1986 (revised in 1996) for transmitting digital audio data between internal devices of a system.

I2S transmits clock signals and data signals separately, so that the receiver does not need to restore the clock from the data signal, reducing the design difficulty of the receiver.

20.2 Features

- Supports master and slave modes
- Supported data formats: LeftJustified/RightJustified/Normal I2S/DSP
- Supports 8/16/24/32-bit data width
- Supports data MSB/LSB switching
- Supports DMA transfer mode
- Supports 4-channel and 6-channel modes in addition to mono/2-channel mode
- Supports playing of mono audio in the 2-channel mode and channel mode swapping
- The 2-channel recording data with less than 16 bits can be merged into FIFO data with less than 32 bits
- Supports 16/32/48/64-bit frame size
- Supports dynamic mute switch function
- TX FIFO has a width of 32 bits and a depth of 16
- RX FIFO has a width of 32 bits and a depth of 16

20.3 Functional Description

Table 20.1: I2S pin list

Name	Type	Description
I2Sx_DI	Input	Serial data input
I2Sx_DO	Output	Serial data output
I2Sx_BCLK	Input/output	Synchronous transmission clock: output (master)/input (slave)
I2Sx_FS	Input/output	Data start/end signal: output (master)/input (slave)

20.4 Functional Description

20.4.1 Data Formats

I2S supports Normal I2S/LeftJustified/RightJustified modes. Normal I2S is a special case of the LeftJustified mode. The mode is set by I2S_CONFIG[17:16].

Normal I2S

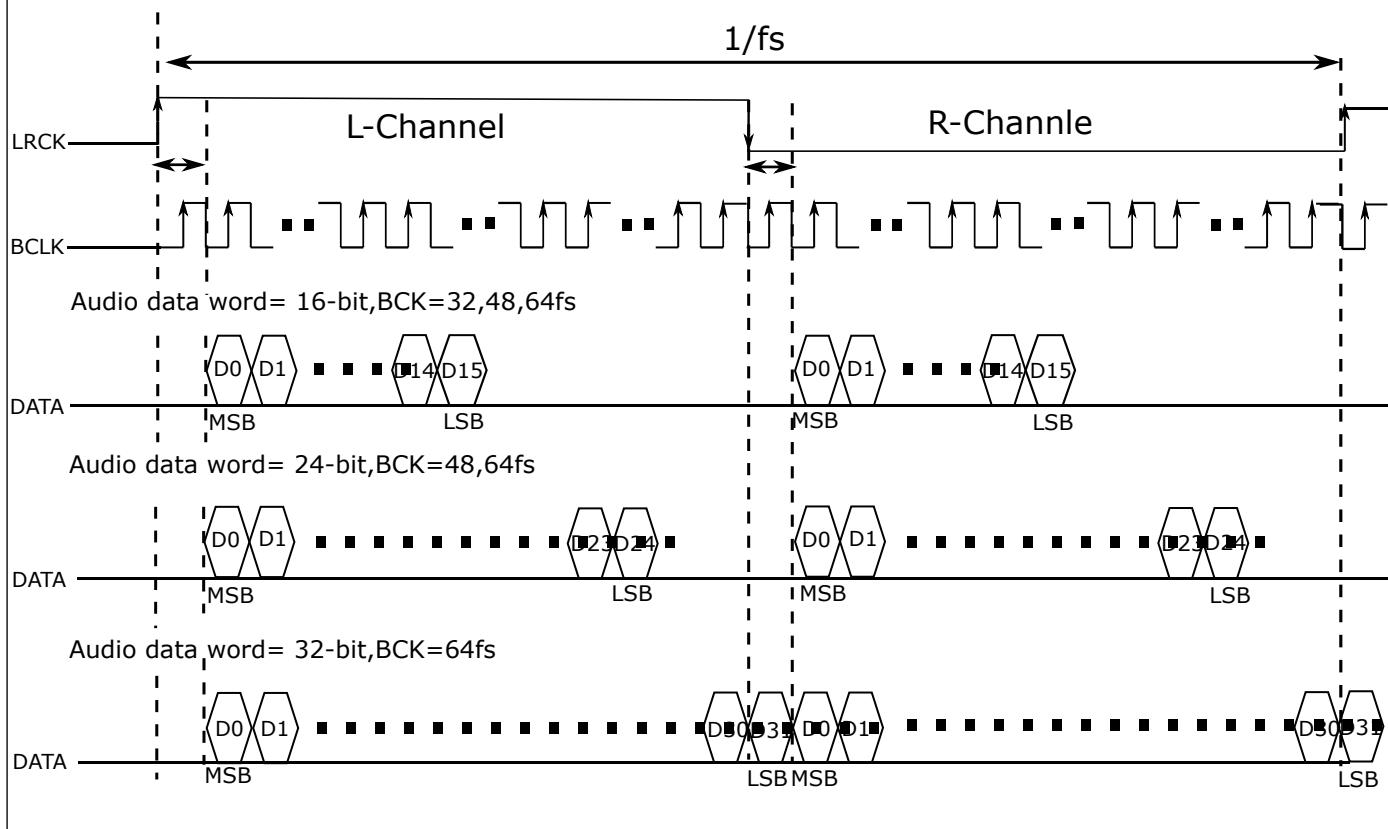

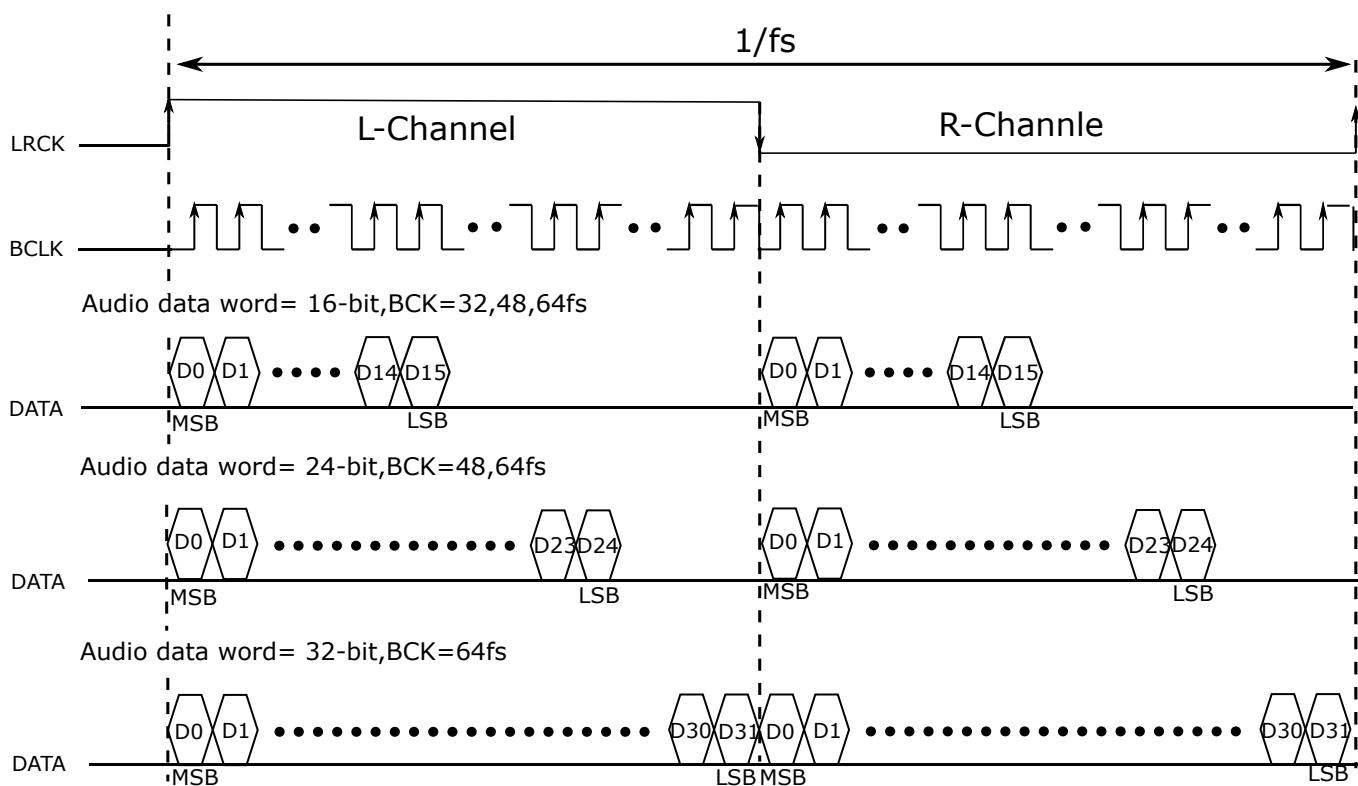

Fig. 20.1: Normal I2S

OFFSET is configured by I2S_CONFIG[25:20]. The only difference between LeftJustified and Normal I2S modes is the different configuration of I2S_CONFIG[25:20].

Left-Justified

Right-Justified

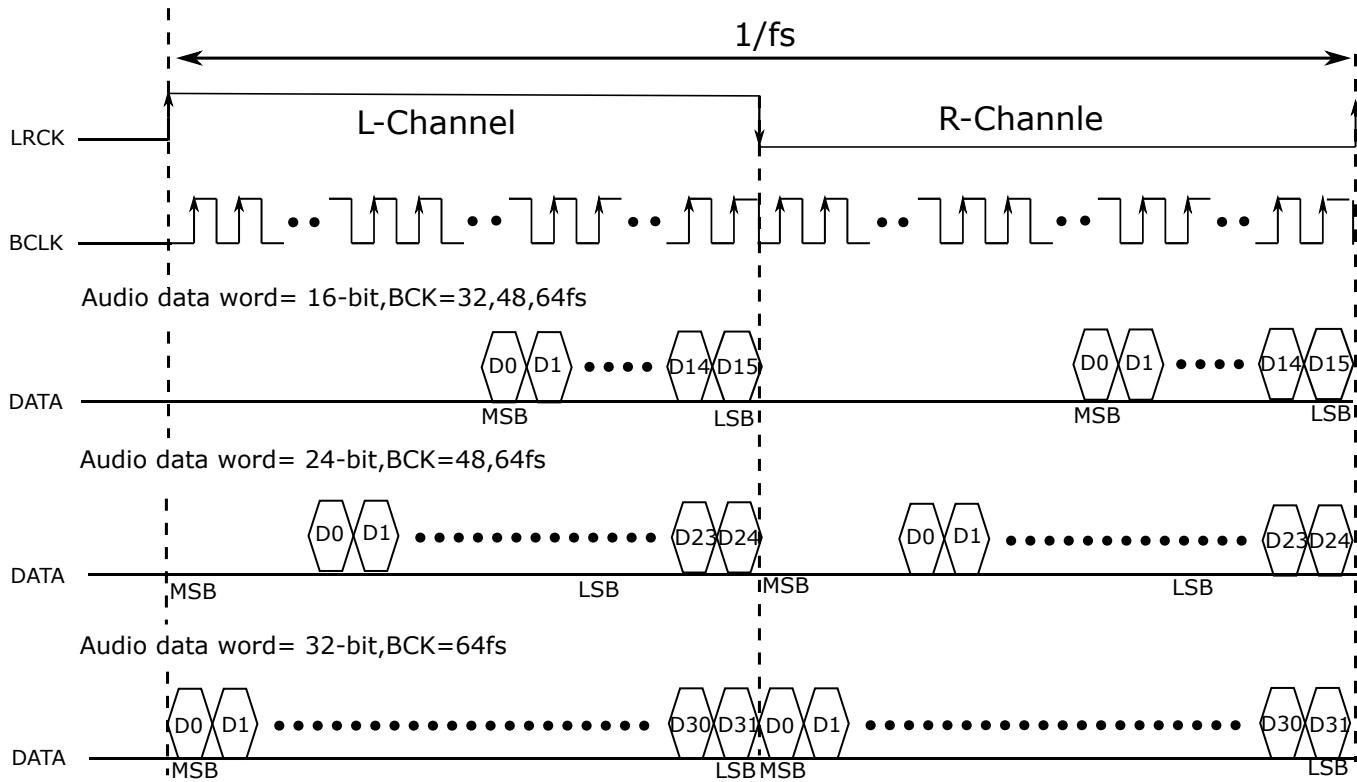

Fig. 20.2: I2S LeftJustified/RightJustified

DSP-MTK TDM64

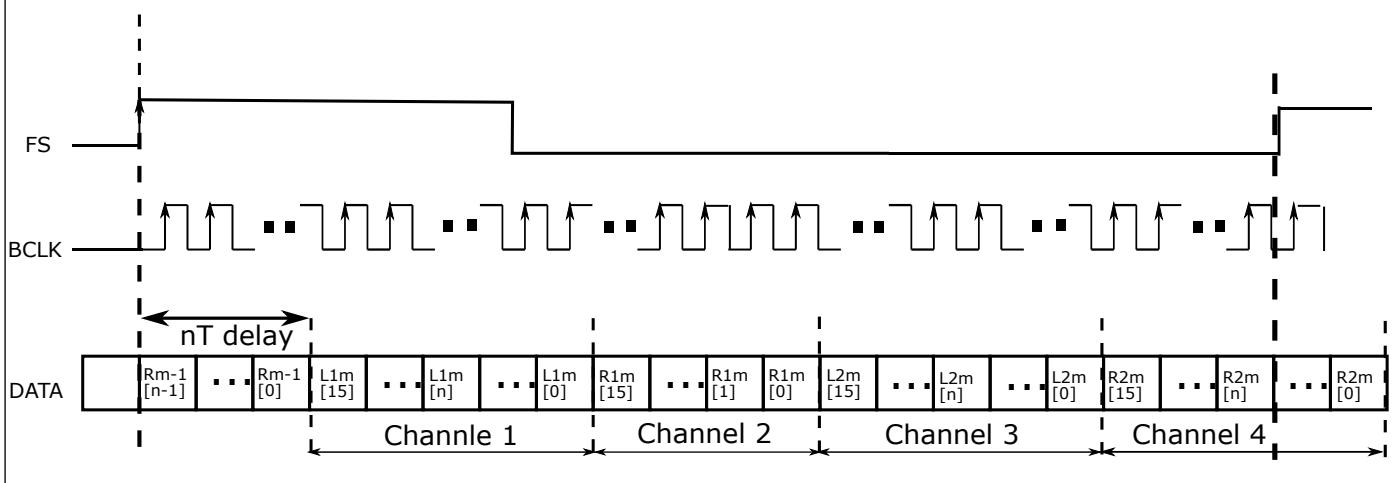

Fig. 20.3: I2S TDM64 Mode—6-Channel Recording

The width of a single pulse is controlled by I2S_CONFIG[6]. When it is set to 0, the width of high-level pulse of FS signal line is the width of data size, and when it is set to 1, that width is 1. Generally, this register is set to 1 in the multi-channel TDM64 mode.

20.4.2 Basic architecture

20.4.3 Clock source

The clock source of I2S is provided by audio PLL, and the clock divider is used to divide the clock source and then generate the clock signal to drive I2S, as shown below:

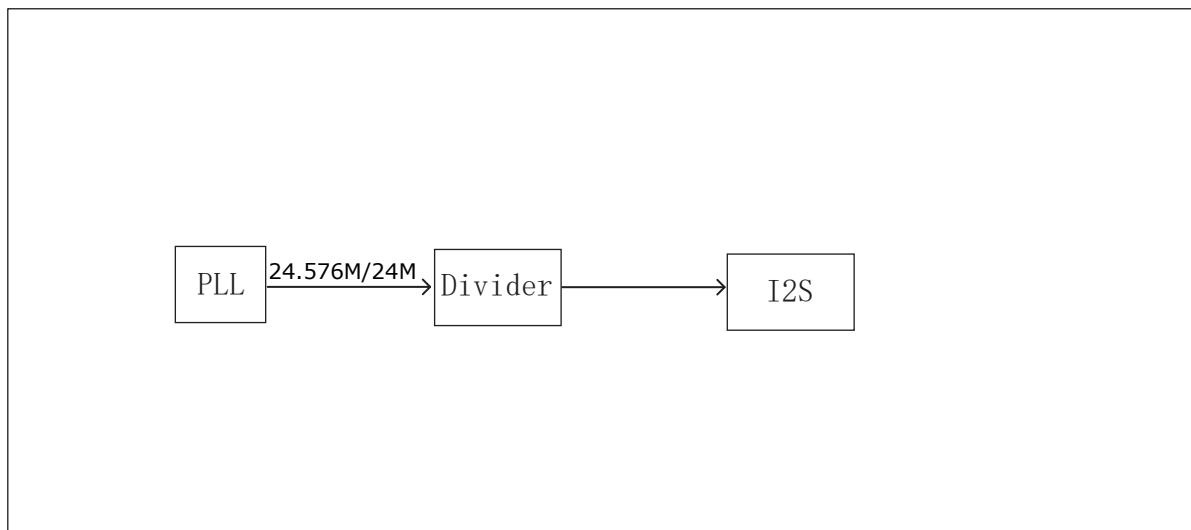

Fig. 20.4: I2S clock

20.4.4 I2S Interrupt

I2S supports the following interrupt control modes:

- TX FIFO request interrupt
- RX FIFO request interrupt
- Overrun/underrun error interrupt

A TX FIFO request interrupt will be generated when TX_FIFO_CNT in I2S_FIFO_CONFIG_1 is greater than TX_FIFO_TH. When the condition is not met, the interrupt flag will be cleared automatically.

A RX FIFO request interrupt will be generated when RX_FIFO_CNT in I2S_FIFO_CONFIG_1 is greater than RX_FIFO_TH. When the condition is not met, the interrupt flag will be cleared automatically.

If the TX/RX FIFO overflows or underflows, it will trigger the error interrupt. When the error disappears, the flag bit will be cleared automatically.

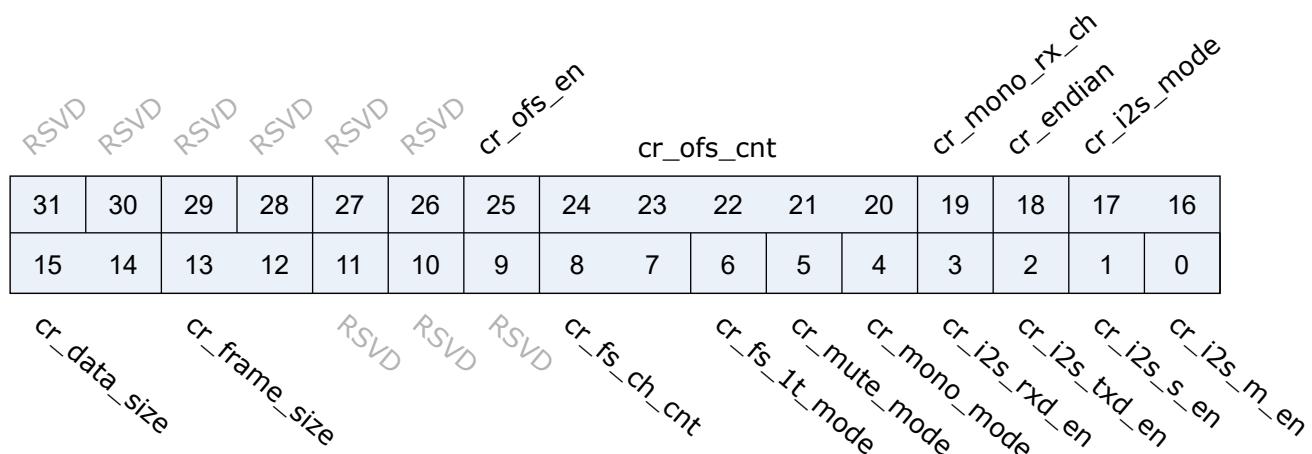

All the interrupt enable bits and interrupt flag bits of I2S are in the I2S_INT_STS register.

21.1 Overview

A PDM audio processing module is built in the chip, supporting recording via the PDM interface microphone.

21.2 Features

- Three 20-bit ADCs are integrated to support three digital PDM inputs.
 - Sampling rate: 8k~96k
 - Signal to noise ratio (AW): 97 dB @ 0 dB gain
 - Harmonic distortion + noise: -87dB @ 0dB gain
 - Analog pre-amplifier gain: 0dB, 6~42 dB, 3dB per gear
- Adjustable high-pass filter and independent digital volume control for ADC channel
- Supports digital PDM interface, with input GPIO multiplexed
- Independent digital volume control
- TX/RX FIFO of 32-bit width
- Supports DMA transfer mode

21.3 Functional Description

The block diagram of PDM module is shown as follows.

PDM has three PDM digital interface demodulators. It passes through the decimation and HPF filters and then goes to the volume control module. Users can control mute/unmute, volume, and audio fade-in/fade-out effect through the volume control module. The recorded data is stored in the FIFO with a depth of 32, and the storage format in FIFO is controlled by the register RX_FIFO_CTRL[25:24]. PDM_RX_FIFO_CTRL[5] configures the resolution of sampling.

PDM only supports PDM audio digital interface input.

21.3.1 PDM Interrupt

PDM supports the following interrupt control modes:

- RX FIFO request interrupt
- RX FIFO underrun interrupt
- RX FIFO overrun interrupt

A RX FIFO request interrupt is generated when RX_DRQ_CNT in RX_FIFO_CTRL is greater than RX_TRG_LEVEL. When the condition is not met, the interrupt flag is cleared automatically.

When there is no data in RX FIFO, but the user enables RX FIFO modulation through RX_CH_EN in RX_FIFO_CTRL, the RX FIFO underrun interrupt is generated.

When the user fills in data that exceeds the maximum depth of RX FIFO, it leads to RX FIFO overflow and cause a RX FIFO overrun interrupt.

21.3.2 FIFO Format Control

PDM_RX_FIFO_CTRL can control the format of the audio data to be stored in FIFO.

The user sets the resolution of audio by configuring PDM_RX_FIFO_CTRL[5].

When 16-bit resolution is selected, the FIFO controller supports the following four data storage formats, which are determined by FIFO_CTRL[25:24].

- Mode 0:

DATA[31:0] = {FIFO[19:14],16' h0}

- Mode 1:

DATA[31:0] = {8{FIFO[19]},FIFO[19:4],8' h0}

- Mode 2:

DATA[31:0] = {12{FIFO[19]},FIFO[19:4],4' h0}

- Mode 3:

DATA[31:0] = {16{FIFO[19]},FIFO[19:4]}

During recording or playing, the conversion result of 32-bit data or the digital audio source to be demodulated is on the left, denoted as DATA[31:0]. The format of data to be stored in FIFO is shown on the right. When the actual resolution of the recording is 20-bit, if the 16-bit resolution is selected, the data with 20-bit resolution must be properly cut. Thus, the high 16 bits of the data with 20-bit resolution are selected as the final result FIFO[19:14] and stored in the position of the high 16 bits, while the low 16 bits are filled with 0. Modes 1, 2, and 3 are expressed in the same

way as Mode 0. The 8{FIFO[19]} symbol indicates that the high 8 bits are padded with the value of bit[19].

Therefore, when a 16-bit resolution is selected, PDM provides four modes to store the digital results of conversion/output.

In the case of 20-bit resolution, the storage formats in the four modes are as follows:

- Mode 0:

DATA[31:0] = {FIFO[19:0],12' h0}

- Mode 1:

DATA[31:0] = {8{FIFO[19]},FIFO[19:0],4' h0}

- Mode 2:

DATA[31:0] = {12{FIFO[19]},FIFO[19:0]}

- Mode 3:

DATA[31:0] = {16{FIFO[19]},FIFO[19:4]}

Distribution of MSB

- Mode 0:

The MSB of data is 31 bits

- Mode 1:

The MSB of data is 23 bits

- Mode 2:

The MSB of data is 19 bits

- Mode 3:

The MSB of data is 15 bits

21.3.3 Startup of FIFO and DMA Transfer

The data in FIFO of the PDM module can be transferred by DMA.

The user can obtain the current amount of valid data in FIFO in real time through the register PDM_RX_FIFO_STATUS.

The FIFO count threshold (8/16/32) for initiating DMA request is selected by configuring FIFO_CTRL[15:14], or can be determined by FIFO_CTRL[22:16].

When the count value is greater than the set threshold, and the FIFO of the channel corresponding to PDM_RX_FIFO_CTRL[12:8] is enabled, a DMA transfer is initiated.

When TX FIFO is started, if there is no valid data in TX FIFO, the tx underrun error will be triggered. Therefore, the

software configuration sequence must be followed.

22.1 Overview

An AUDIO processing module is built in the chip, supporting pdm/analog interface microphone recording and stereo playback.

22.2 Features

- Three 20-bit ADCs are integrated to support three analog mic differential inputs
 - Sampling rate: 8k~96k
 - Signal to noise ratio (AW): 97 dB @ 0 dB gain
 - Harmonic distortion + noise: -87 dB @ 0 dB gain
 - Analog pre-amplifier gain: 0 dB, 6~42 dB, 3 dB per gear
- A low-noise bias power supply with adjustable voltage supplies power to the analog MIC, and the adjustment range is 1.8 V~2.5 V
- Adjustable high-pass filter and independent digital volume control for ADC channel
- A 5-band parametric equalizer for ADC channel
- Support digital mic interface, with input GPIO multiplexed
- Integrated with two 20-bit DACs that support two analog LINEOUT differential outputs with ramp power-on function
 - Sampling rate: 8k~192k
 - Signal to noise ratio (AW): 103dB @ 0dB gain
 - Harmonic distortion + noise: -90dB @ 0dB gain
 - Analog output gain: 0 dB, 6~42 dB, 3 dB per gear

- Independent digital volume control that supports soft volume adjustment/mute, suitable for DAC playback channel
- A 10-band parametric equalizer supporting dynamic range control and flexible adjustment, suitable for DAC playback channel
- Supports voice activity detection that suits low-power voice wakeup applications
- TX/RX FIFO of 32-bit width
- Supports DMA transfer mode

22.3 Functional Description

The block diagram of AUDIO is shown as follows.

AUDIO has three ADCs, which are connected to the volume control module after performing PGA gain and passing through decimation and HPF filters. Users can control mute/unmute, volume, and audio fade-in/fade-out effect through the volume control module. The 5-band EQ filter can improve the audio performance, perform gain and attenuation in each frequency band of the audio, and thus optimize the recording timbre. AGC will adjust volume according to the amplitude of audio data, to enhance the recording performance and reduce the top distortion of recording. The built-in VAD wakeup module can distinguish the noise signal from the useful audio signal in the environment, and when a valid audio signal is detected, a VAD_INT event will be generated. The recorded data will be stored in the FIFO with a depth of 32, and the storage format in FIFO is controlled by the register RX_FIFO_CTRL[25:24]. RX_FIFO_CTRL[5] configures the resolution of sampling. The PDM digital interface or analog microphone interface can be used as the recording data interface, and the interface type is controlled by the DAC_0[12] DAC_0[15] DAC_0[18] bit.

AUDIO has two DACs. After being taken out from FIFO, processed by the audio mixer and EQ filter, undergone volume control and inserted into the filter, the data is modulated into analog signal for driving the speaker to play. The audio mixer can mix the audio data read out from FIFO with the recording data of ADC channel. The EQ filter performs gain reduction on each frequency band, thus changing the timbre of the played audio. The volume control module will control the audio volume and the fade-in/fade-out effect.

22.3.1 AUDIO Interrupt

AUDIO 有着丰富的中断控制，包括以下几种中断模式：

AUDIO supports the following interrupt control modes:

- TX FIFO request interrupt
- TX FIFO underrun interrupt
- TX FIFO overrun interrupt
- RX FIFO request interrupt
- RX FIFO underrun interrupt

- RX FIFO overrun interrupt
- Recording volume adjustment interrupt
- Playback volume adjustment interrupt
- VAD interrupt

A TX FIFO request interrupt will be generated when TX_DRQ_CNT in TX_FIFO_CTRL is greater than TX_TRG_LEVEL. When the condition is not met, the interrupt flag will be cleared automatically.

When there is no data in TX FIFO, but the user enables TX FIFO modulation through TX_CH_EN in TX_FIFO_CTRL, the TX FIFO underrun interrupt will be generated.

When the user fills in data that exceeds the maximum depth of TX FIFO, it will lead to TX FIFO overflow and cause a TX FIFO overrun interrupt.

A RX FIFO request interrupt will be generated when RX_DRQ_CNT in RX_FIFO_CTRL is greater than RX_TRG_LEVEL. When the condition is not met, the interrupt flag will be cleared automatically.

When there is no data in RX FIFO, but the user enables RX FIFO modulation through RX_CH_EN in RX_FIFO_CTRL, the RX FIFO underrun interrupt will be generated.

When the user fills in data that exceeds the maximum depth of RX FIFO, it will lead to RX FIFO overflow and cause a RX FIFO overrun interrupt.

When the recording volume of ADC is completely adjusted, it will trigger the ADC volume adjustment completion interrupt. In general application scenarios, the volume adjustment of ADC is completed immediately.

When the playback volume of DAC is completely adjusted, it will trigger the DAC volume adjustment completion interrupt. As the playback of DAC supports fade-in/fade-out effect, the volume adjustment may not be completed immediately. The adjustment time depends on the register DAC_H_CTRL_MODE.

22.3.2 FIFO Format Control

TX_FIFO_CTRL and RX_FIFO_CTRL (collectively FIFO_CTRL, as they are the same) decide the format of audio data stored in FIFO.

Users select the resolution of audio by configuring FIFO_CTRL[5].

When 16-bit resolution is selected, the FIFO controller supports the following four data storage formats, which are determined by FIFO_CTRL[25:24].

- Mode 0:
 - DATA[31:0] = {FIFO[19:14],16' h0}
- Mode 1:
 - DATA[31:0] = {8{FIFO[19]},FIFO[19:4],8' h0}

- Mode 2:
 - DATA[31:0] = {12{FIFO[19]}, FIFO[19:4], 4' h0}
- Mode 3:
 - DATA[31:0] = {16{FIFO[19]}, FIFO[19:4]}

During recording or playing, the conversion result of 32-bit data or the digital audio source to be demodulated is on the left, denoted as DATA[31:0]. The format of data to be stored in FIFO is shown on the right. When the actual resolution of the recording is 20-bit, if the 16-bit resolution is selected, the data with 20-bit resolution must be properly cut. Thus, the high 16 bits of the data with 20-bit resolution are selected as the final result FIFO[19:14] and stored in the position of the high 16 bits, while the low 16 bits are filled with 0. Modes 1, 2, and 3 are expressed in the same way as Mode 0. The 8{FIFO[19]} symbol indicates that the high 8 bits will be padded with the value of bit[19].

Therefore, when a 16-bit resolution is selected, AUDIO provides four modes to store the digital results of conversion/output.

In the case of 20-bit resolution, the storage formats in the four modes are as follows:

- Mode 0:
 - DATA[31:0] = {FIFO[19:0], 12' h0}
- Mode 1:
 - DATA[31:0] = {8{FIFO[19]}, FIFO[19:0], 4' h0}
- Mode 2:
 - DATA[31:0] = {12{FIFO[19]}, FIFO[19:0]}
- Mode 3:
 - DATA[31:0] = {16{FIFO[19]}, FIFO[19:4]}

Distribution of MSB

- Mode 0:
 - The MSB of data is 31 bits
- Mode 1:
 - The MSB of data is 23 bits
- Mode 2:
 - The MSB of data is 19 bits
- Mode 3:
 - The MSB of data is 15 bits

22.3.3 Startup of FIFO and DMA transfer

The data in FIFO of the AUDIO module can be transferred by DMA.

The user can obtain the current amount of valid data in FIFO in real time through the register RX_FIFO_STATUS/TX_FIFO_STATUS.

The FIFO count threshold (8/16/32) for initiating DMA request is selected by configuring FIFO_CTRL[15:14], or can be determined by FIFO_CTRL[22:16].

When the count value is greater than the set threshold, and the FIFO of the channel corresponding to TX_FIFO_CTRL[9:8] or RX_FIFO_CTRL[12:8] is enabled, a DMA transfer will be initiated.

When TX FIFO is started, if there is no valid data in TX FIFO, the tx underrun error will be triggered. Therefore, the software configuration sequence must be followed.

23.1 Overview

The chip is equipped with a PSRAM controller that can drive various types of PSRAM.

23.2 Features

- Supports up to 200 MHz PSRAM clock
- Supports linear burst and warp burst modes

23.3 Functional Description

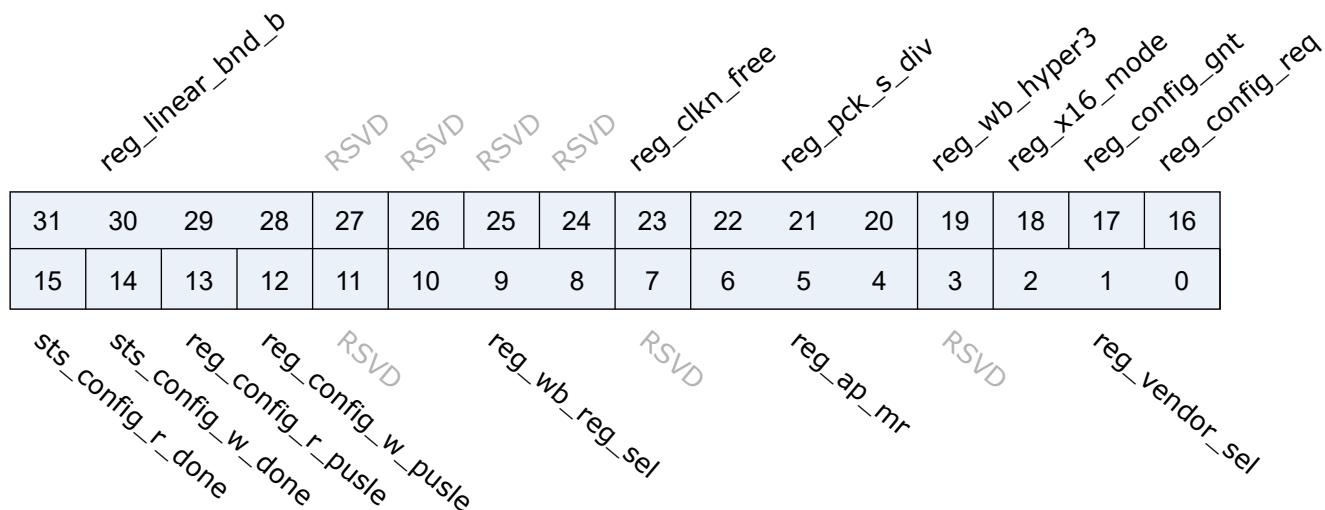

The PSRAM controller can read and write the internal registers and memory of various types of PSRAM.

24.1 Overview

The EMAC module is a 10/100Mbps Ethernet Media Access Controller (Ethernet MAC) compatible with IEEE 802.3. It consists of status and control register set, RX/TX module, RX/TX buffer descriptor (BD) set, master interface, MDIO interface, and physical layer chip (PHY) interface.

The status and control register set contains the status and control bits of EMAC. As the interface with the user program, it controls data sending and receiving and reports the status.

The RX/TX module obtains data frames from the specified memory according to the control words in the RX/TX descriptor, adds preamble and CRC, and expands short frames to send them through PHY. Or, it receives data from PHY, and puts them into the specified memory according to the RX/TX BD. Relevant event flags are set after sending and receiving are completed. If the event interrupt is enabled, an interrupt request will be sent to the master for processing.

MDIO and MII/RMII interfaces communicate with PHY, including reading and writing the registers of PHY and sending and receiving data packets.

24.2 Features

- Compatible with the MAC layer defined by IEEE 802.3
- PHY supporting MII/RMII interface defined by IEEE 802.3
- Interacts with PHY through MDIO interface
- Supports 10 Mbps and 100 Mbps Ethernet
- Supports half-duplex and full-duplex
- Supports automatic flow control and control frame generation in the full-duplex mode
- Supports collision detection and retransmission in the half-duplex mode

- Supports the generation and verification of CRC
- Generates and removes data frame preamble
- Supports automatic extension of short data frames when sending
- Detects too long/short data frames (length limit)
- Transmits long data frames (> standard Ethernet frame length)
- Automatically discards data packets with over-limit retransmission times or too small frame gap
- Broadcast packet filtering
- Internal RAM for storing up to 128 BDs
- Splits and configures a data packet to multiple consecutive BDs when sending
- Various event flags sent or received
- Generates a corresponding interrupt when an event occurs

24.3 Functional Description

The composition of EMAC module is as follows.

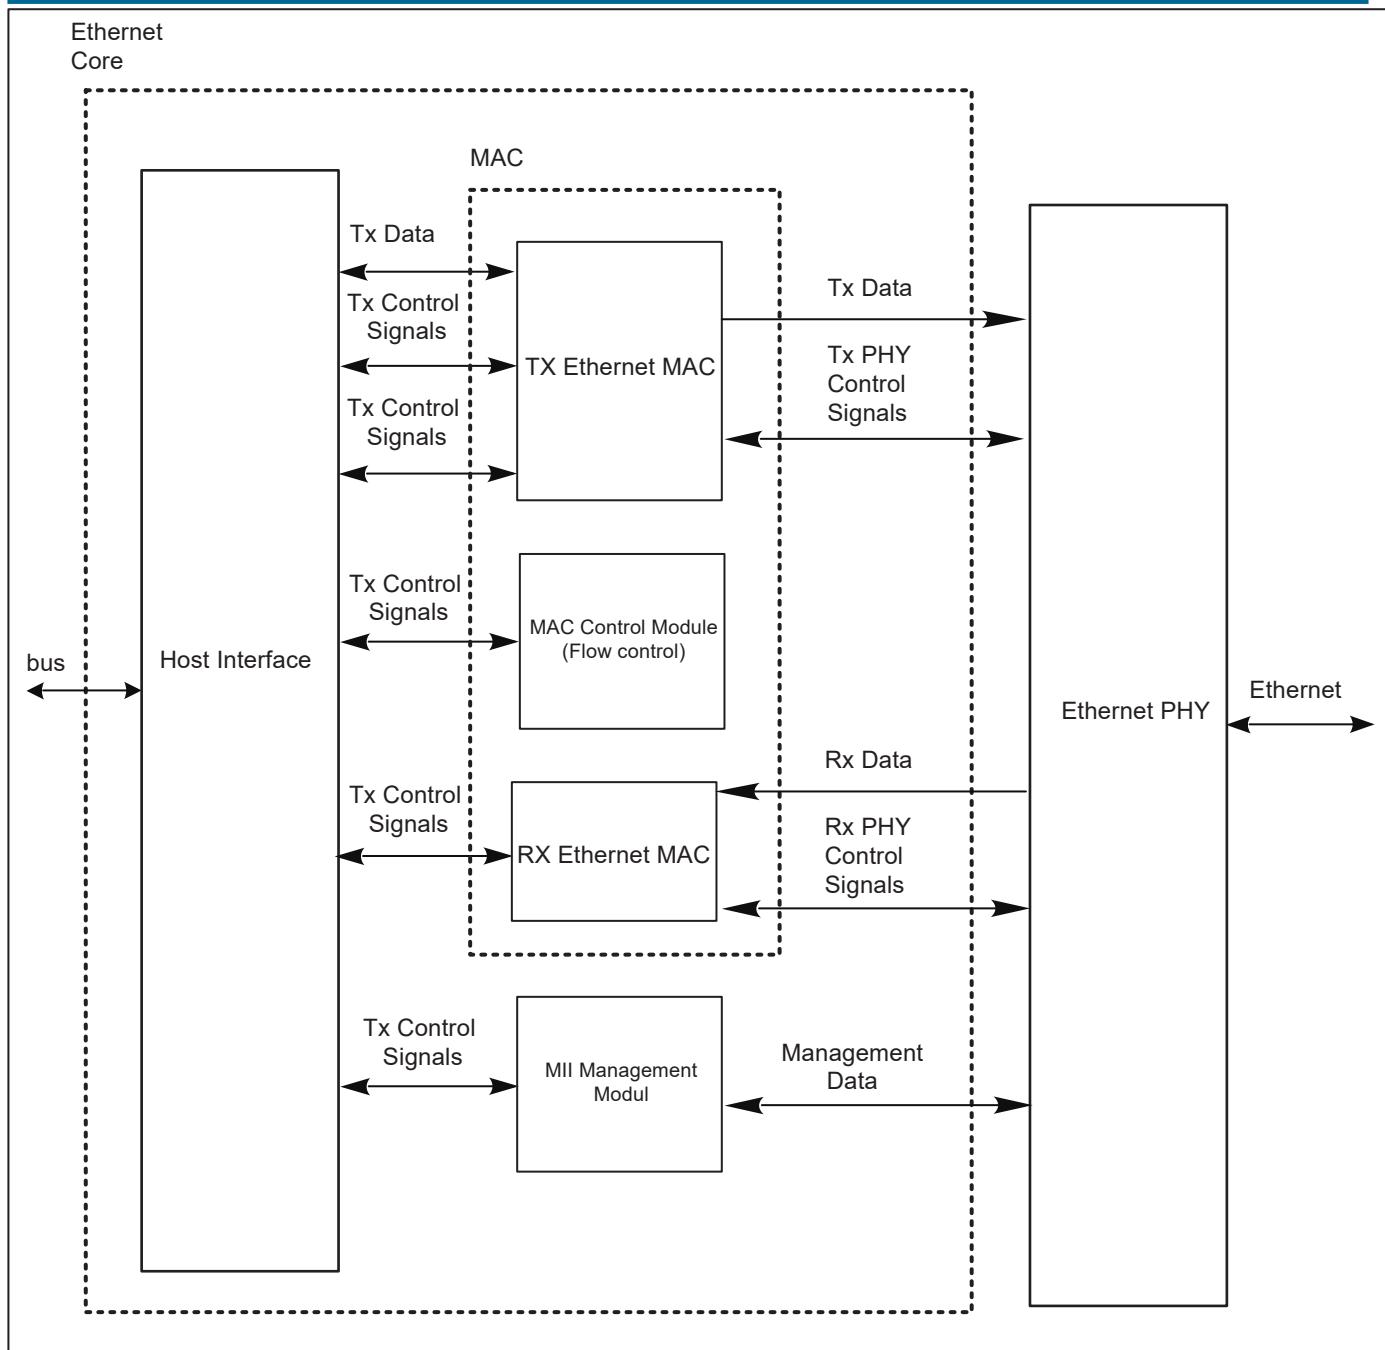

Fig. 24.1: Block diagram of EMAC

Through MDIO interface, the control register can read and write PHY's registers, to perform configuration, mode selection (half/full duplex), negotiation, and other operations. The RX module filters and checks the received data frames for a valid preamble, FCS, and length, and stores the data in the specified memory address according to the BD. The TX module gets data from the memory according to the data BD, adds preamble, FCS, and pad, and then sends them out using the CSMA/CD protocol. If CRS is detected, retry will be delayed. The RX/TX BD set is connected to the system RAM, which is used to store the sent and received Ethernet data frames. Each descriptor contains the corresponding control status word and buffer memory address. There are 128 descriptors for RX/TX, and can be allocated flexibly.

24.4 Clock

EMAC needs a clock for synchronous transmission and reception (25 MHz (MII) or 50 MHz (RMII) at 100 Mbps, and 2.5 MHz at 10 Mbps). The clock must be synchronized between EMAC and PHY.

24.5 RX/TX BD

The RX/TX BD provides the association between EAMC and data frame cache address information, controls RX/TX data frames, and gives RX/TX status prompt. Each descriptor consists of two consecutive words (1 word = 32 bits). The word with low address provides the length, control bits, and status bits of the data frames contained in this buffer. The word with high address is the memory pointer. More details of BD are presented in the register description section. It should be noted that BD must be written by word. EMAC supports 128 BDs, which are shared by the RX/TX logic and can be freely combined. But the TX BD always occupies the preceding contiguous area. The number of BD is specified by the TXBDNUM field in the register MAC_TX_BD_NUM. EMAC circularly processes the RX/TX BDs according to their order, until it finds the BDs marked WR, and goes back to the first RX/TX BD respectively.

24.6 PHY Interaction

The interactive register set of PHY provides a way to communicate commands and data needed for interaction with PHY. EMAC controls the working mode of PHY through MDIO interface, and ensures the matching of both working modes (such as rate, full/half-duplex). Data packets interact between EMAC and PHY through MII/RMII interface, which is selected by the RMII_EN bit in the EMAC's mode register (EMAC_MODE): When this bit is 1, RMII mode is selected, and otherwise the MII mode is selected. Both MII and RMII modes support the transmission rates of 10 Mbps and 100 Mbps specified in IEEE 802.3u. The transmission signals of MII and RMII are described as follows.

Table 24.1: Transmission signal

Name	MII	RMII
EXTCK_EREFCK	ETXCK: Send clock signal	EREFCK:reference clock

ERX0-ERX3	ERX0ERX3: 4-bit received data	ERX0ERX1: 2-bit received data
ERXER	ERXER: Receive error indication	ERXER: Receive error indication
ERXCK	ERXCK: Receive clock signal	-
ETXEN	ETXEN: TX enable	ETXEN: TX enable
ETX0-ETX3	ETX0ETX3: 4-bit sent data	ETX0ETX1: 2-bit sent data
ETXER	ETXER: Send error indication	-
EMDC	MDIO Clock	MDIO Clock
EMDIO	MDIO Data Input Output	MDIO Data Input Output

The RMII interface has fewer pins, and 2-bit data lines are used for transmission and reception. At 100 Mbps, a reference clock of 50 MHz is required.

24.7 Programming Flow

24.7.1 PHY initialization

- Select a proper connection mode by setting the RMII_EN bit in the register EMAC_MODE according to the PHY type.
- Set the MAC address of EMAC to EMAC_MAC_ADDR0 and EMAC_MAC_ADDR1
- Set an appropriate clock for the MDIO part by programming the CLKDIV field in the register EMAC_MIIMODE
- Set the address of the corresponding PHY to the FIAD field of the register EMAC_MIIADDRESS
- According to PHY's manual, send commands through registers EMAC_MIICOMMAND and EMAC_MIIITX_DATA
- Store the data read from PHY in the register EMAC_MIIRX_DATA
- Query the status of interaction with PHY commands through the register EMAC_MIISTATUS

After basic interaction is completed, PHY shall be switched to the auto-negotiation state. Upon negotiation completed, the mode must be programmed to the FULLD bit in the EMAC_MODE register based on the negotiation result.

24.7.2 Send Data Frame

- Configure data frame format and interval bit fields in the register EMAC_MODE
- Specify the number of TX BDs by setting the TXBDNUM field in the register EMAC_TX_BD_NUM, so that the rest is the number of RX BDs
- Prepare the data frames to be sent in the memory
- Fill in the address of data frames in the data pointer field (word 1) corresponding to the TX BDs
- Clear the status flag in the control and status fields (word 0) corresponding to the TX BDs, and set the control field (CRC enable, PAD enable, and interrupt enable)
- Write the data frame length, and set the RD field to inform EMAC that this BD data needs to be sent. If necessary, set the upper IRQ bit to enable interrupt
- Especially, if it is the last TX BD, the upper WR bit must be set. EMAC will "go back" to the first TX BD after this BD is processed
- If there are multiple BDs to be sent, repeat the steps of setting BD to pad all the TX BDs
- If one packet is contained in only one BD, set its EOF bit to 1
- If one packet is sent in multiple BDs, just mark the last BD it occupies as the end of the packet by setting the EOF

bit

- To enable the TX interrupt, configure the TX-related bits in the register EMAC_INT_MASK
- Configure the TXEN bit in the register EMAC_MODE to enable TX
- If an interrupt is enabled, in the TX interrupt, obtain the current BD through the TXBDNUM field in the register EMAC_TX_BD_NUM
- Complete processing based on the status word of the current BD
- For BDs whose data has been sent, the RD bit in its control field will be cleared by hardware and BDs will not be used for TX again. Only after new data is padded and RD is set, can this BD be used for TX again

24.7.3 Receive Data Frame

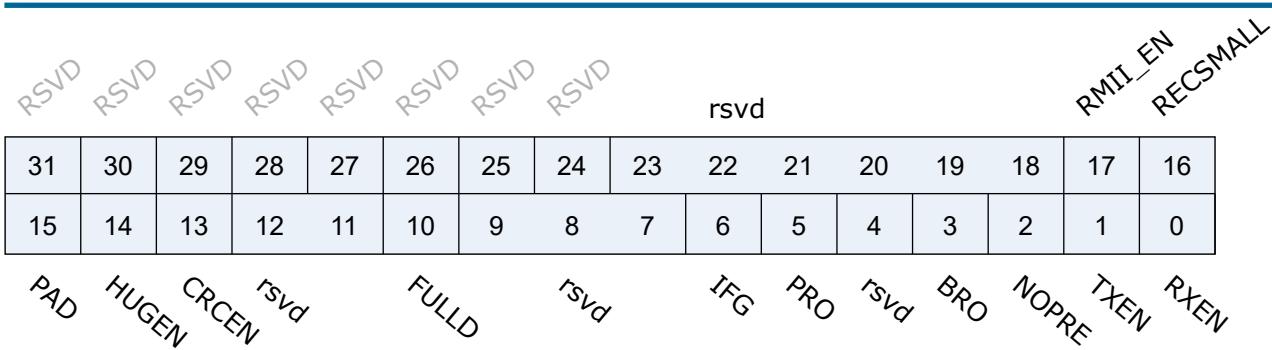

- Configure data frame format and interval bit fields in the register EMAC_MODE
- Specify the number of TX BDs by setting the TXBDNUM field in the register EMAC_TX_BD_NUM, so that the rest is the number of RX BDs
- Prepare an area in memory for receiving data
- Fill in the address of data frames in the data pointer field (word 1) corresponding to the RX BDs
- Clear the status flag in the control and status fields (word 0) corresponding to the RX BDs, and set the control field (interrupt enable)
- Write the receivable data frame length, and set the E-bit field to inform EMAC that this BD is free and can receive data. If necessary, set the upper IRQ bit to enable the interrupt
- Especially, if it is the last valid RX BD, the upper WR bit must be set. EMAC will "go back" to the first RX BD after this BD is processed
- If there are multiple BDs for receiving data, repeat the steps of setting BD to pad all the BDs
- To enable the RX interrupt, configure the RX-related bits in the register EMAC_INT_MASK
- Configure the RXEN bit in the register EMAC_MODE to enable RX
- If an interrupt is enabled, in the RX interrupt, obtain the current BD through the RXBDNUM field in the register EMAC_TX_BD_NUM
- Complete processing based on the status word of the current BD
- For BDs whose data has been received, the E bit in its control field will be cleared by hardware and BDs will not be used for RX again. Only after you take out the data and set the E bit, can this BD be used for RX again

25.1 Overview

Universal Serial Bus (USB) is an external bus standard that establishes specifications for the connection and communication between computers and external devices. xx supports USB 2.0 (HighSpeed + FullSpeed) and can be used as a host controller (Host) or a peripheral controller (Device). As a Host, it contains a USB Host that supports all-speed transactions. Without software intervention, the Host can handle the transaction-based data structure by itself to reduce the load of CPU, and automatically send and receive data on the USB bus. As a Device, each endpoint except endpoint 0 supports the transfer types in the USB specification to adapt to various applications. In addition, xx's USB controller complies with the OTG standard and supports the session request protocol (SRP) and host negotiation protocol (HNP).

25.2 Features

- Compatible with USB 2.0 (HighSpeed + FullSpeed)
- Compatible with OTG revision1.3
- UTMI + Level 3
- OTG SRP and HNP protocols
- Host, OTG, and Device modes
- Supports LPM
- Compatible with EHCI data structure (FSTN and SITD unsupported)
- Nine endpoints (EP0: control endpoint EP1EP8: interrupt/isolation/bulk endpoint)
- One dedicated FIFO for control transmission and four general FIFOs (control FIFO: 64 bytes; general FIFO: 512 bytes)
- Supports 2-FIFO and 3-FIFO modes

- Supports DMA
- Supports VDMA

25.3 Functional Description

25.3.1 Operating Steps of USB

1. Configure internal transceiver
2. Configure USB controller
3. Configure USB interrupt
4. Configure USB DMA/VDMA (direct reading and writing of FIFO by CPU is unsupported)
5. Finish

25.3.2 Partial Register Configuration and Functional Description

25.3.3 Interrupt Processing Flow for USB Enumeration Phase

26.1 Overview

The SD Host Controller (SDH) is used to control the communication with SDIO or SD card, and all accesses are set through standard control registers.

26.2 Features

- Comply with the SD Host Controller Specification defined by the SD Association
- Suitable for SDIO/SD memory card
- Supports the standard register settings for the SDH
- Supports the DMA operation for high-speed data transfer
- Supports interrupt
- Supports data block transmission

26.3 Functional Description

26.3.1 SDH Overall Structure

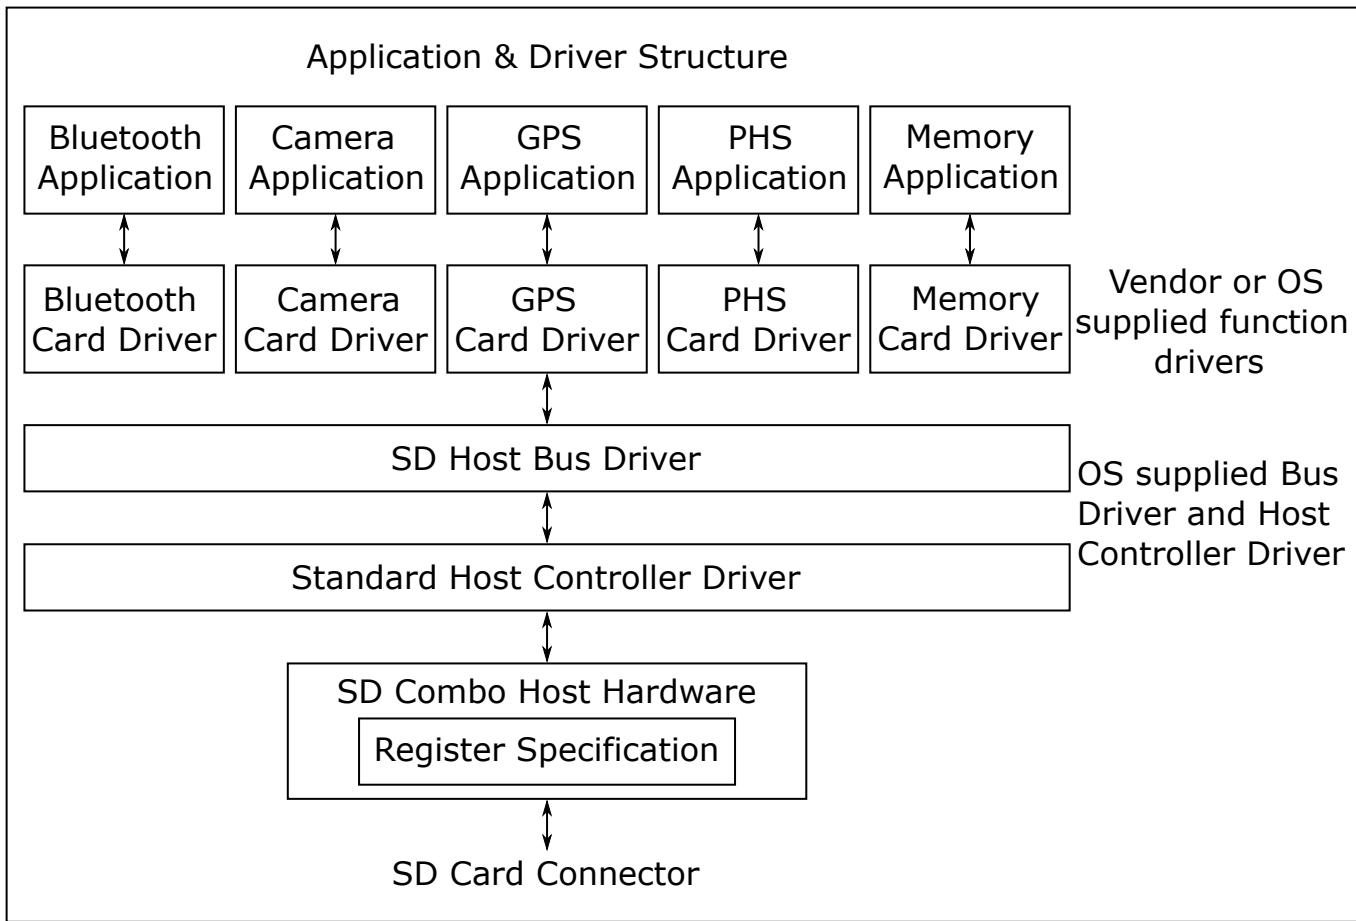

Fig. 26.1: SDH Hardware and Driver Structure

26.3.2 Register Mapping

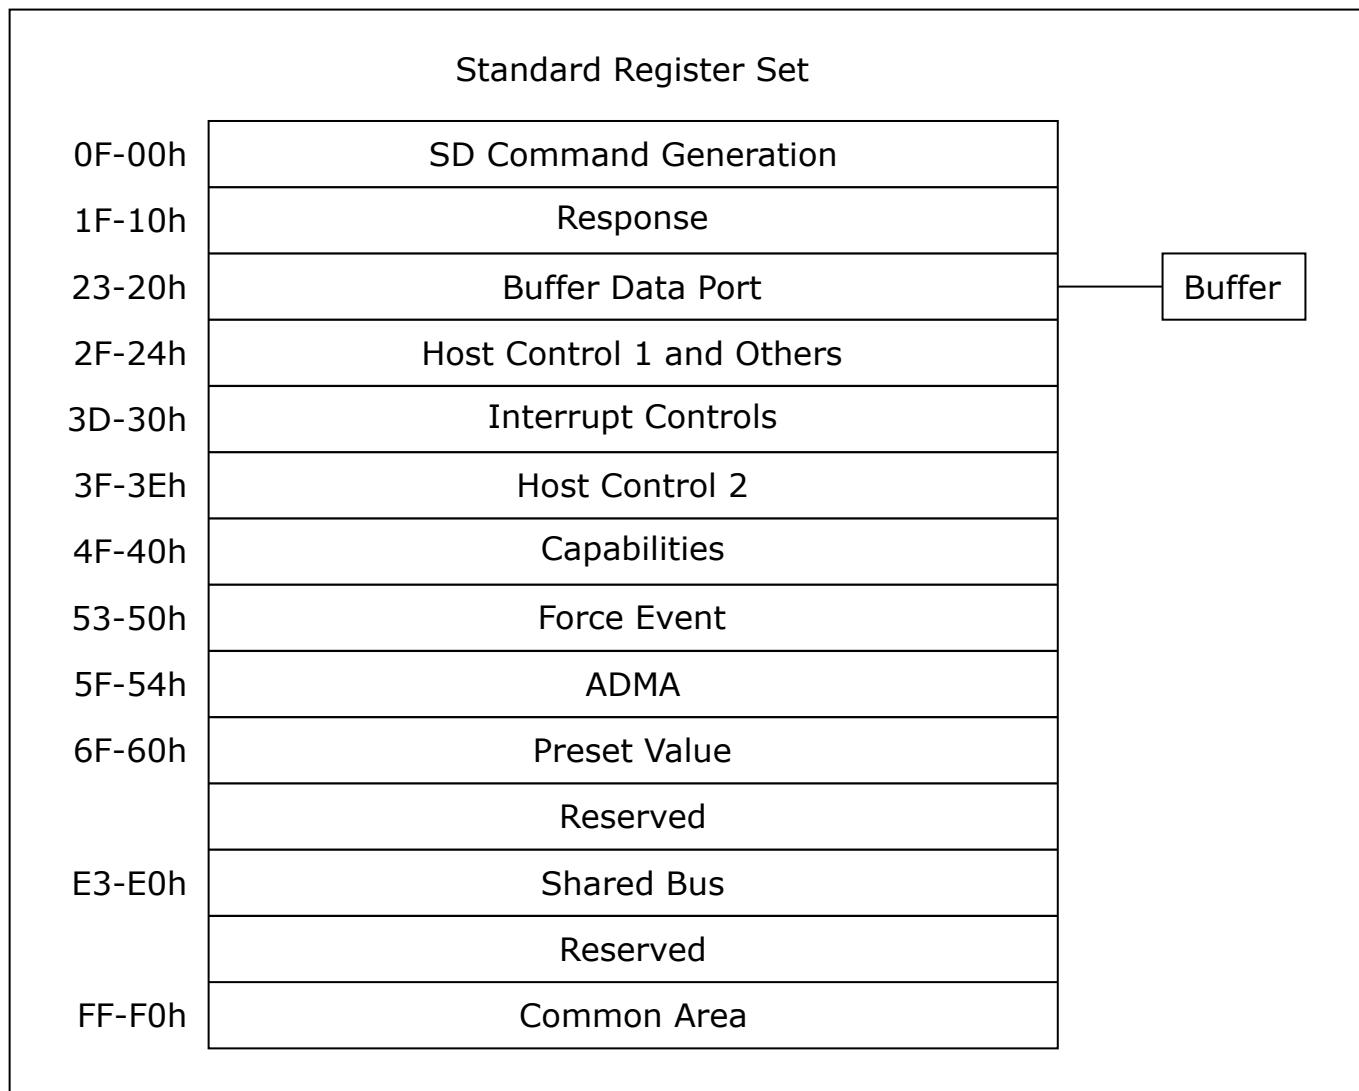

Fig. 26.2: Standard Register Mapping Classification

- SD Command Generation: parameter used to generate SD command
- Response: the response value from the card
- Buffer Data Port: the data access port of the internal buffer
- Host Control 1 and Others: current status, SD bus control, host reset, etc.
- Interrupt Controls: Interrupt Status and Interrupt Enable
- Host Control 2: vendor-specific host controller support information
- Capabilities: expansion of host control register
- Force Event: a test register that generates events through software

- ADMA: advanced DMA register
- Preset Value: preset values for clock frequency selection and driving strength selection
- Shared Bus: device control of shared bus system
- Common Area: public information area

26.3.3 Support for Multiple Card Slots

A standard register set is defined for each card slot. If the host controller has two card slots, two register sets are required. Each card slot is independently controlled. This makes it possible to support the combination of bus interface voltage, bus timing and SD clock frequency.

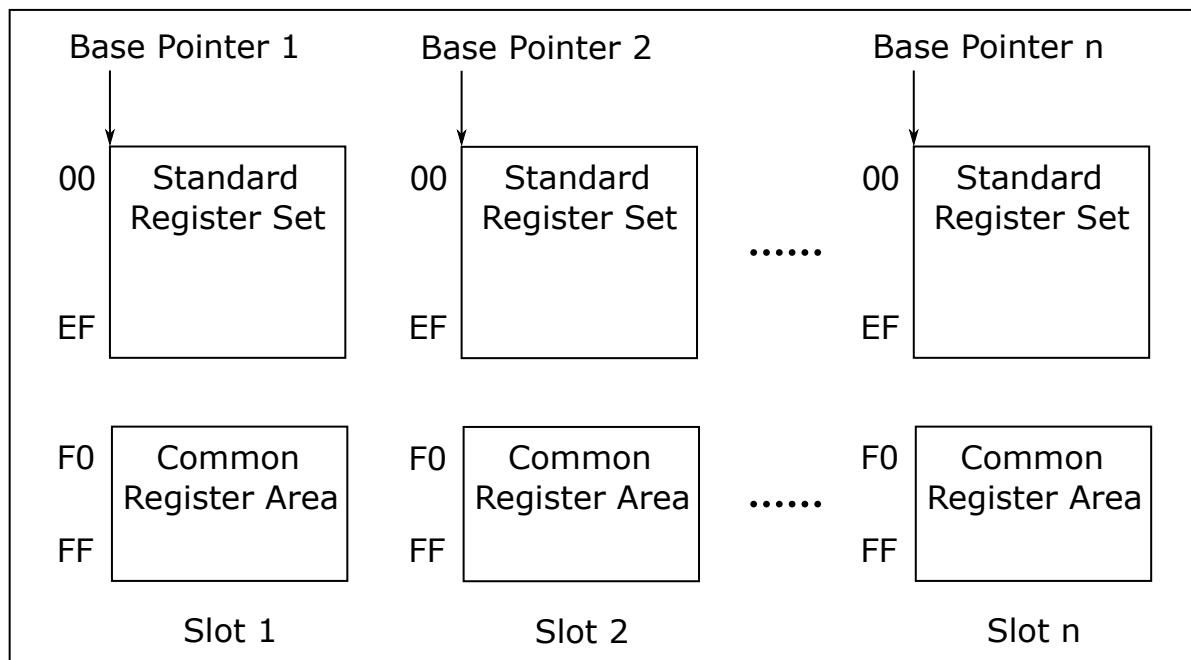

Fig. 26.3: Register Mapping of Multi-Card Slot Controller

The above figure shows the register mapping of the multi-card slot host controller. The host driver shall use PCI configuration registers or the vendor-specific methods to determine the number of card slots and the base pointer to the standard register set of each card slot. The offset from 0F0h to 0FFh is reserved for the common register area, which defines the information of card slot control and public state. The common register area can be accessed from the register set of any card slot. This allows the software to control each card slot independently, because it can access the Card Slot Interrupt Status register and the Host Controller Version register from each register set.

26.3.4 Supporting DMA

The host controller provides a “programmed I/O” method for the host driver to transfer data using the Buffer Data Port register. Optionally, host controller implementers may support data transfer using DMA. Prior to using DMA, the host driver shall confirm that both the host controller and the system bus support it (PCI bus can support DMA). DMA shall support both single block and multiple-block transfers. The host controller registers shall remain accessible for issuing non-DAT line commands during a DMA transfer execution. The result of a DMA transfer shall be the same regardless of the system bus data transfer method. The host driver can stop and restart a DMA operation by the control bits in the block gap control register. By setting Stop At Block Gap Request, a DMA operation can be stopped at block gap. By setting Continue Request, DMA operation can be restarted. If an error occurs, DMA operation shall be stopped. To abort DMA transfer, the host driver shall reset the host controller through the “Software Reset” of DAT line in the software reset register, and issue CMD12 when executing read/write commands on multiple blocks.

26.3.5 SD Command Generation

	SDMA Command	ADMA Command	CPU Data Transfer	Non-DAT Transfer
SDMA System Address /Argument 2	Yes /No	No /Auto CMD23	No /Auto CMD23	No /No
Block Size	Yes	Yes	Yes	No (Protected)
Block Count	Yes	Yes	Yes	No (Protected)
Argument 1	Yes	Yes	Yes	Yes
Transfer Mode	Yes	Yes	Yes	No (Protected)
Command	Yes	Yes	Yes	Yes

Fig. 26.4: Register for Generating SD Commands

The table above shows the register settings (offset from 000h to 00Fh in a register set) required for three types of transactions: DMA-generated transfer (SDMA or ADMA), CPU data transfer (using “programmed I/O”) and non-DAT transfer. When starting a transaction, the host driver shall program these registers from 000h to 00Fh. The offset of the starting register can be calculated based on the transaction type. The last written offset shall always be 00Fh, because the high byte written to the command register will trigger the SD command. During a data transaction, the host driver shall not read the SDMA system address, block size and block count registers, unless transfer is stopped or suspended because the values are changing and unstable. To prevent data transfer from damaging registers when commands are issued, the block size, block count and transfer mode registers shall be write-protected by the host controller, and the command disable (DAT) shall be set to 1 in the current status register (this signal cannot protect the SDMA system address). When command disable (CMD) is set to 1, the host driver must not write parameter 1

and command register.

26.3.6 Suspend and Resume Mechanism

Support for Suspend/Resume can be determined by checking Suspend/Resume Support in the Capabilities register. When the SD card accepts a suspend request, the host driver saves information in the first 14 bytes registers (that is, offsets 000h-00dh) before issuing other SD commands. On resuming, the host driver restores these registers and then issues the Resume command to continue suspended operation. The SDIO card sets the DF (Resume Data Flag) in the response to the Resume command. (Since the Suspend and Resume commands are CMD52 operations, the response data is actually the Function Select Register in the CCCR.) If DF is set to 0, it means that the SDIO card cannot continue data transfer while suspended. This bit can be used to control data transfers and interrupt cycles. If the Resume Data Flag is set to 0, no more data is transferred and an interrupt cycle is started if the transaction being resumed is in 4-bit mode. If DF is set to 1, data transfers continue. It is worth noting that to use Suspend/Resume function, the SDIO card must support Suspend and Resume commands and Read Wait control.

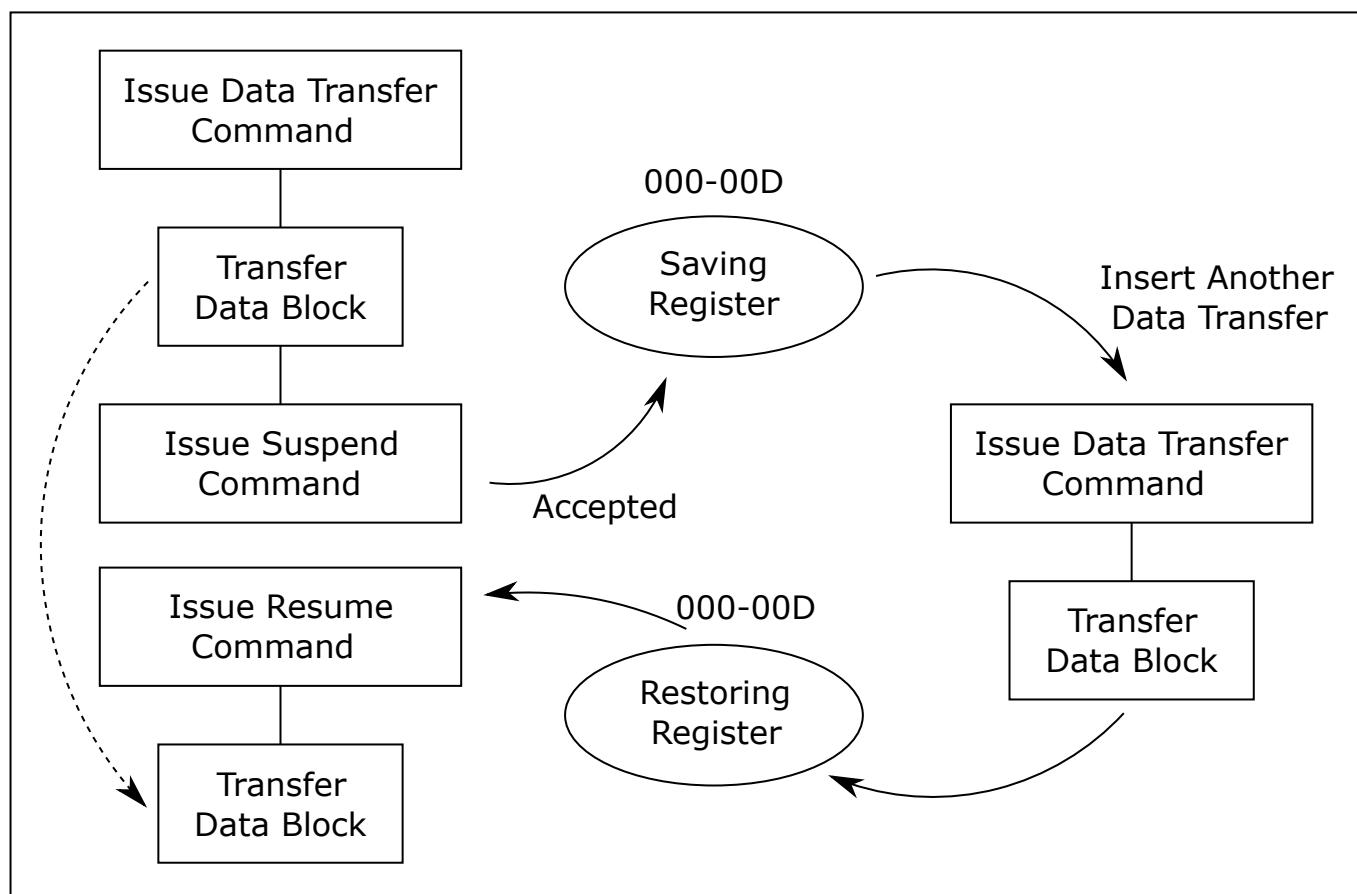

Fig. 26.5: Suspend and Resume Mechanism

26.3.7 Buffer Control

The host controller has a data buffer for data transfer. The host driver accesses internal buffer through the 32-bit Buffer Data Port register. Here are some rules for accessing the buffer.

26.3.7.1 Control of Buffer Pointer

Internally, the host controller maintains a pointer to control the data buffer. The pointer is not directly accessible by the host driver. Every time the Buffer Data Port register is accessed, the pointer is incremented depending on amount of data written to the buffer. In order to accommodate a variety of system buses, this pointer shall be implemented regardless of system bus width (8/16/32/64-bit system bus width can be supported).

26.3.7.2 Determination of Buffer Block Length

To transfer data blocks at a burst, the relationship between host controller and SD card buffer sizes is very important. The host driver shall use the same data block length for both host controller and SD card. If the controller and card buffer sizes are different, the host driver shall use the smaller one. The maximum host controller buffer size is defined by the Max Block Length field in the Capabilities register.

26.3.7.3 Dividing Large Data Transfer

The SDIO command CMD53 defines the maximum data size for transfer according to the following formula: Maximum data size = block size x block count. For example, the block size is specified by the buffer size, and the maximum value of block count is 512 (9-bit count), as specified in the command parameter CMD53. In the worst case, if the card only has a 1-byte buffer, CMD53 can be used to transfer 512 bytes of data at most (block size = 1, block count = 512). If the card does not support the multi-block mode, only one byte can be transferred. If an application or card driver wants to transfer data with a larger size, the host driver shall divide the large-size data into multiple CMD53 blocks.

26.3.8 Relationship Between Interrupt Control Registers

The host controller implements a number of interrupt sources. Interrupt sources can be enabled as interrupts or as system wakeup signals. If the interrupt source's corresponding bit in the Normal Interrupt Status Enable or Error Interrupt Status Enable register is 1 and the interrupt becomes active, its active state is latched and made available to the host driver in the Normal Interrupt Status register or the Error Interrupt Status register. Interrupt Status shall be cleared when Interrupt Status Enable is cleared. An interrupt source with its bit set in an Interrupt Status register shall assert a system interrupt signal if its corresponding bit is also set in the Normal Interrupt Signal Enable register or the Error Interrupt Signal Enable register. Once signaled, most interrupts are cleared by writing a 1 to the associated bit in the Interrupt Status register. Card interrupts, however, shall be cleared by the card driver. If a card interrupt is generated, the host driver may clear Card Interrupt Status Enable to disable card interrupts while the card driver is

processing them. After all interrupt sources are cleared, the host driver sets it again to enable another card interrupt. Disabling the Card Interrupt Status Enable avoids generating multiple interrupts during interrupt service processing. The Wakeup Control register enables Card Interrupt, Card Insertion, or Card Removal status changes to be configured to generate a system wakeup signal. These interrupts are enabled or masked independently of the Normal Interrupt Signal Enable register. The kind of wakeup event can be read from the Normal Interrupt Status register. The interrupt signal and wakeup signal are logical ORed and shall be read from the Slot Interrupt Status register.

26.3.9 Hardware Block Diagram and Timing Part

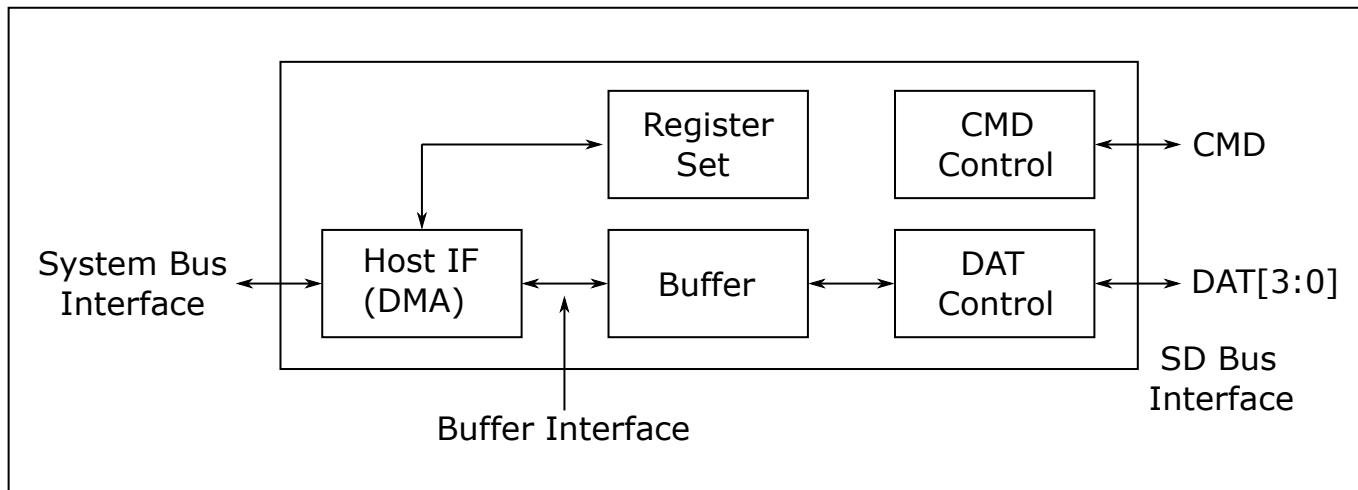

Fig. 26.6: Block Diagram of Host Controller

The host controller has two bus interfaces, the system bus interface and the SD bus interface. The host controller assumes that these interfaces are asynchronous, that is, working at different clock frequencies. The host driver is on system bus time, because it is software executed by the host controller CPU on its system clock. The SD card is on SD bus time. That is, its operation is synchronized by SDCLK. The host controller shall synchronize signals to communicate between these interfaces. Data blocks shall be synchronized at the buffer module. All status registers shall be synchronized by the system clock and maintain synchronization during output to the system interface. Control registers, which trigger SD bus transactions, shall be synchronized by SDCLK. Therefore, there will be a timing delay when propagating signals between the two interfaces. This means that the host driver cannot do real time control of the SD bus and needs to rely on the host controller to control the SD bus according to register settings. The buffer interface enables internal read and write buffers. The transfer complete interrupt status indicates completion of the read/write transfer for both DMA and non-DMA transfers. However, this timing is different between reads and writes. Read transfers shall be completed after all valid data have been transferred to the host system and are ready for the host driver to access. Write transfers shall be completed after all valid data have been transferred to the SD card and the busy state is over.

26.3.10 Auto CMD12

Multiple block transfers for SD memory require CMD12 to stop the transactions. The host controller automatically issues CMD12 when the last block transfer is completed. This feature of the host controller is called Auto CMD12. The host driver shall set Auto CMD12 Enable in the Transfer Mode register when issuing a multiple block transfer command. Auto CMD12 timing synchronization with the last data block shall be done by hardware in the host controller. Commands that do not use the DAT line can be issued during multiple block transfers. These commands are referred to using the notation CMD_wo_DAT. To prevent DAT line commands and CMD_wo_DAT commands from conflicting, the host controller shall arbitrate the timing by which each command is issued on the SD Bus. Therefore, a command might not immediately be issued after the host driver writes to the Command register. The command may be issued before or after Auto CMD12, depending on the timing. To be able to distinguish the responses of DAT line and CMD_wo_DAT commands, the Auto CMD12 response can be determined from the upper four bytes of the Response register (at offset 01Ch in the standard register set). If errors related to Auto CMD12 are detected, the host controller shall issue an Auto CMD error interrupt. The host driver can check the Auto CMD12 error status (Command Index/End bit/CRC/Timeout Error) by reading the Auto CMD Error Status register. If the Auto CMD12 was not executed, the host driver needs to recover from the CMD_wo_DAT error and issue CMD12 to stop the multiple block transfer. If the CMD_wo_DAT was not executed, the host driver can issue it again after recovering from the Auto CMD12 error. In UHS mode SDR104, the host driver shall use Auto CMD23 to stop multiple block read/write operation instead of using Auto CMD12. In other bus speed modes, if the card supports CMD23, the host driver shall use Auto CMD23 instead of using CMD12.

26.3.11 Controlling SDCLK

This table shows how SDCLK is controlled by the SD Bus Power in the Power Control register and the SD Clock Enable in the Clock Control register.

SD Bus Power	SD Clock Enable	State of SDCLK
Change 0 to 1	0	Drive Low
	1	Start Clock With Specified Period Of High
Change 1 to 0	0	Drive Low
	1	Drive Low Immediately
0	Don't Care	Drive Low
1	Change 0 to 1	Start Clock With Specified Period Of High
	Change 1 to 0	Maintains Period Of High And Then Stops Clock And Drive Low

Fig. 26.7: Controlling SDCLK by the SD Bus Power and SD Clock Enable

The clock period of SDCLK is specified by the SDCLK Frequency Select in the Clock Control register and the Base Clock Frequency For SD Clock in the Capabilities register. Since the SD card may use both clock edges, the duty

ratio of SD clock shall be average 50% (scattering within 45-55%) and the Period of High should be half of the clock period. The oscillation of SDCLK starts from driving specified Period of High. When SDCLK is stopped by the SD Clock Enable, the host controller shall stop SDCLK after driving Period of High to maintain the duty ratio of clock. When SDCLK is stopped by the SD Bus Power, the host controller shall stop SDCLK immediately (drive Low) and SD Clock Enable shall be cleared.

26.3.12 Advanced DMA

The SD Host Controller Standard Specification Version 2.00 defines the advanced DMA (ADMA) transfer algorithm. The DMA algorithm defined in the SD Host Controller Standard Specification Version 1.00 is called single DMA (SDMA). The disadvantage of SDMA is that the DMA interrupt generated at every page boundary disturbs CPU to reprogram the new system address. This SDMA algorithm develops a performance bottleneck by interrupting at each page boundary. ADMA adopts the scatter gather DMA algorithm so that higher data transfer speed is available. Before executing ADMA, the host driver can program a list of data transfers between system memory and SD card to the descriptor table. It enables ADMA to run without interrupting the host driver. In addition, ADMA supports both 32-bit system memory addressing and 64-bit system memory addressing. The 32-bit system memory addressing uses the lower 32-bit field of the 64-bit address register. ADMA is divided into ADMA1 and ADMA2. ADMA1 only supports the transfer of 4KB aligned data in the system memory. ADMA2 optimizes this restriction, so that the data of any size at any location can be transferred in the system memory. The formats of descriptor tables are different among them. In this document, the term “ADMA” refers to ADMA2.

26.3.12.1 Block Diagram of ADMA2

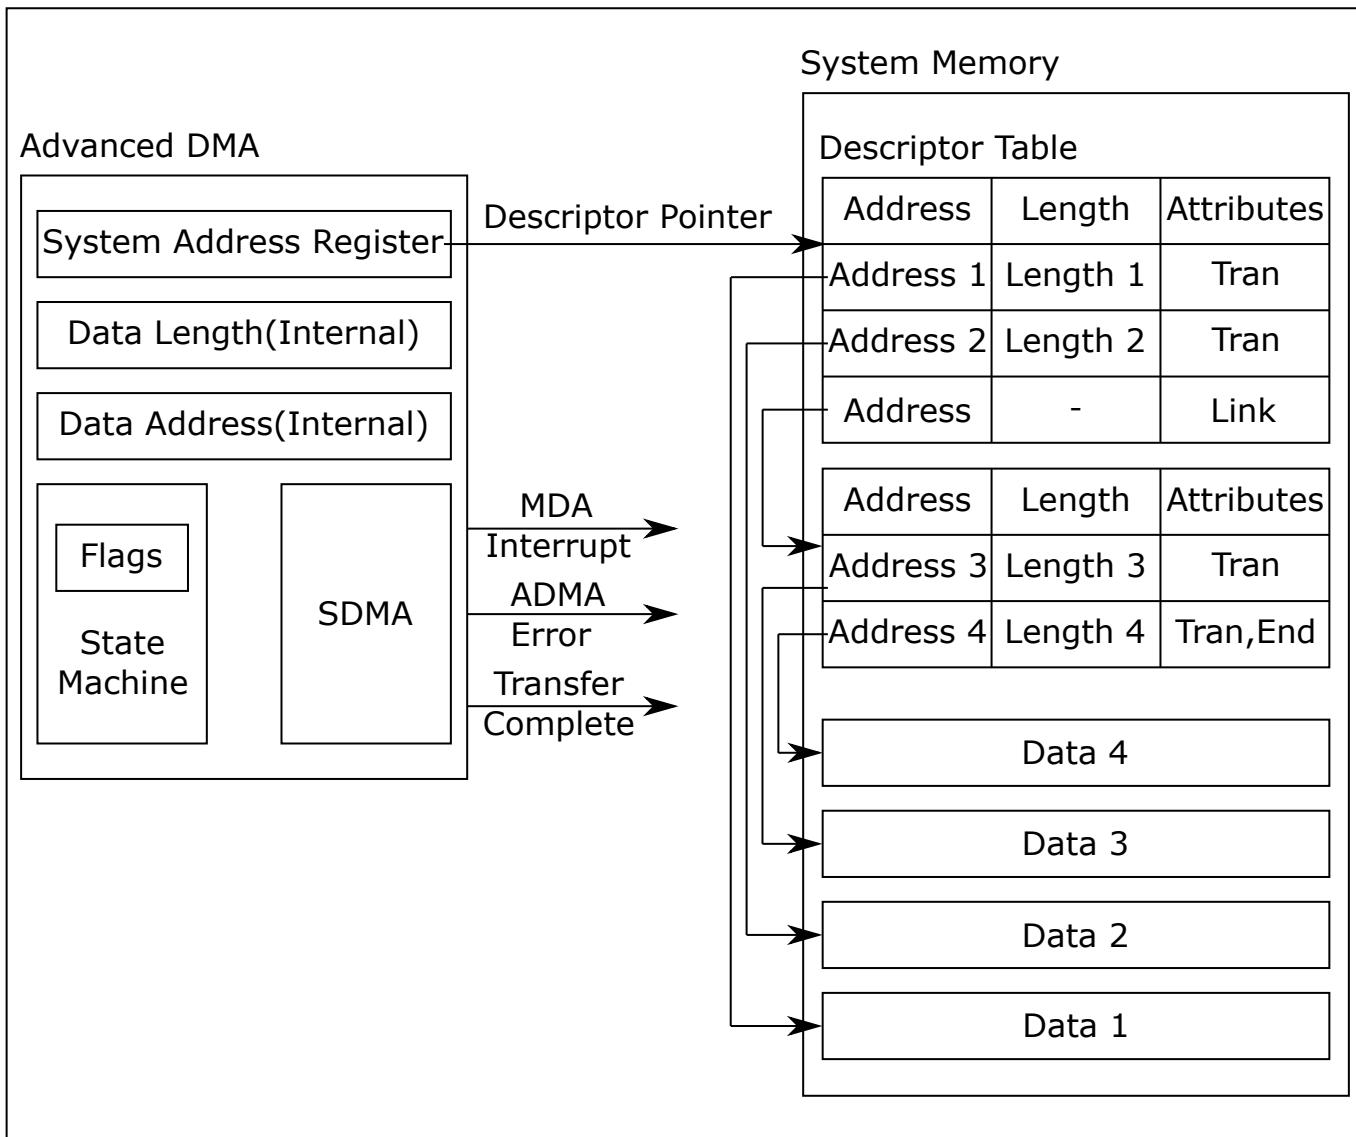

Fig. 26.8: Block Diagram of ADMA2

The descriptor table is created by the host driver in the system memory. The 32-bit address descriptor table is used for the 32-bit addressing system, and 64-bit address descriptor table is used for the 64-bit addressing system. Each descriptor line (one executable unit) consists of address, length and attribute fields. This attribute specifies the operation of the descriptor line. ADMA2 consists of SDMA, state machine and register circuit. ADMA2 uses the 64-bit advanced DMA system address register (offset 058h) as the descriptor pointer, instead of the 32-bit SDMA system address register (offset 0). Writing to the command register triggers the termination of ADMA2 transfer. ADMA2 takes a descriptor line and executes it. This process is repeated until the end of the descriptor (the attribute “end” equals to 1) is found.

26.3.12.2 Data Address and Data Length Requirements

There are three requirements for programming descriptors:

- The minimum unit of address is 4 bytes.
- The maximum data length of each descriptor line is less than 64 KB.
- Total length = length 1 + length 2 + length 3 + ⋯ + length n = multiple of block size.

If the total length of the descriptor is not a multiple of the block size, the ADMA2 transfer may not be terminated. In this case, the transfer shall be terminated by data timeout. The block count register allows the transfer of maximum 65,535 blocks. If the ADMA2 operation is less than or equal to the transfer of 65,535 blocks, the block count register can be used. In this case, the total length of the descriptor table shall be equal to the product of the block size and the block count. If the ADMA2 operation exceeds the transfer of 65,535 blocks, the block count register shall be disabled by setting Block Count Enable to 0 in the transfer mode register. In this case, the length of data transfer is not specified by the block count but by the descriptor table. Thus, the timing of detecting the last block on the SD bus may be different, and it affects the control of read transfer activity, write transfer activity and DAT line activity in the current status register. In the case of a read operation, multiple blocks may be read. If the read operation is for the last memory area, the host driver shall ignore the OUT_OF_RANGE error.

26.3.12.3 Descriptor Table

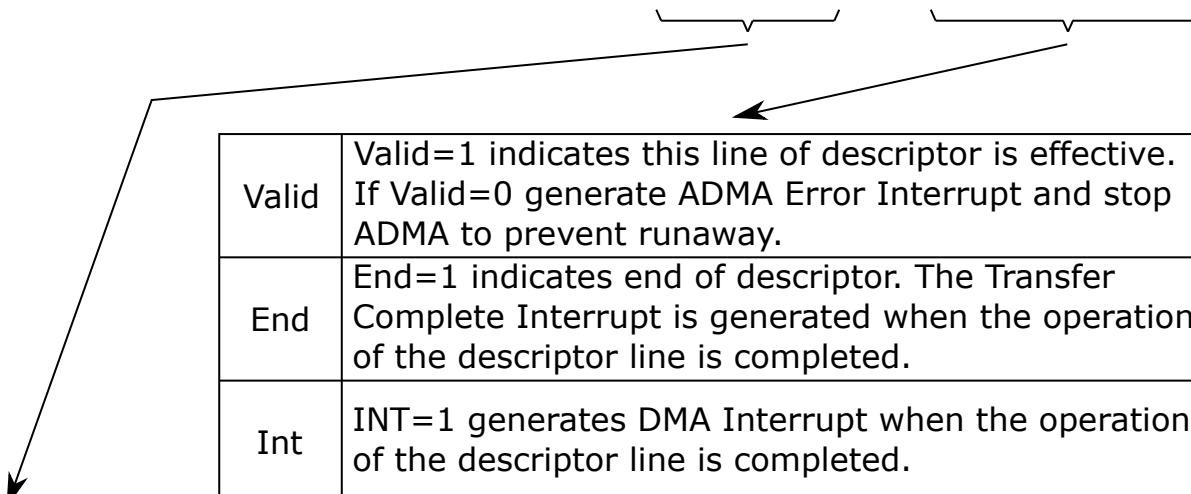

Address Field		Length		Reserved		Attribute																																																																	
63	32	31	16	15	06	05	04	03	02	01	00

1	1	Link	Link Descriptor	Link to another descriptor.																																																																			

Fig. 26.9: 32-Bit Address Descriptor Table

The above figure shows the definition of the 32-bit address descriptor table. One descriptor line consumes 64 bits (8 bytes) of memory space. The attribute is used to control descriptors. Three action symbols are specified here. The “Nop” operation skips the current descriptor line and goes to the next line. The “Tran” operation transfers the data specified by the address and length fields. The “Link” operation is used to link two separate descriptors. The link address field points to the next descriptor table. The combination of Act2=0 and Act1=1 is reserved and defined as the same operation as “Nop”. Future versions of the controller may use this field and redefine new operations. The 32-bit address is stored in the lower 32 bits of the 64-bit address register. For a 32-bit address descriptor table, the address field shall be set on the 32-bit boundary (the lower 2 bits are always set to 0).

26.3.12.4 ADMA2 State

This figure illustrates the four states of ADMA2: fetch descriptor state, change address state, transfer data state and stop ADMA state:

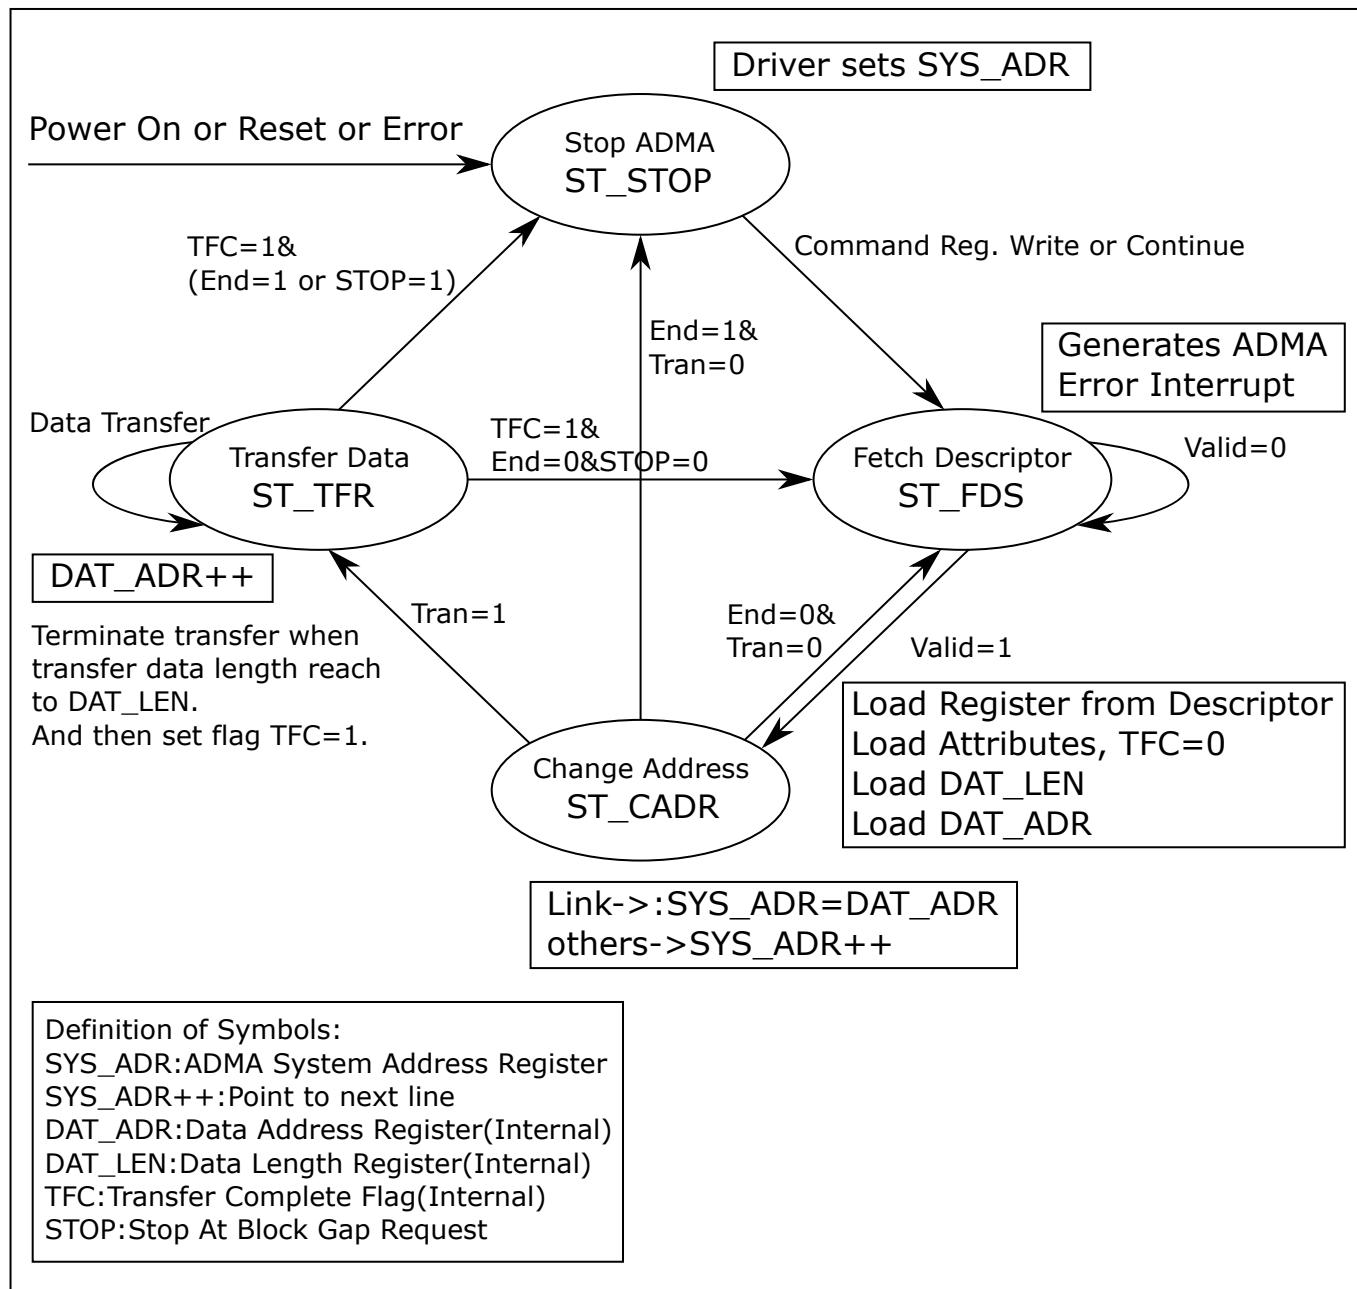

Fig. 26.10: ADMA2 States

- ST_FDS (fetch descriptor): ADMA2 fetches the descriptor line and sets the parameters in the internal register, and then switches to the ST_CADR state.
- ST_CADR (change address): The “Link” operation loads another descriptor address into the ADMA system address register. In other operations, the ADMA system address register is incremented to the next descriptor

line. If End=0, it switches to the ST_TFR state. Even if some errors occur, ADMA2 must not stop in this state.

- ST_TFR (transfer data): The data of one descriptor line is transferred between system memory and SD card. If data transfer continues (End=0), it switches to the ST_FDS state. If data transfer is completed, it switches to the ST_STOP state.
- ST_STOP (stop DMA): ADMA2 will remain in this state in these cases: after power-on reset or software reset; all the descriptor data has been transferred. It switches to the ST_FDS state if a new ADMA2 operation is started by writing to the command register.

ADMA2 does not support the Suspend/Resume function, but can use the Stop and Resume functions. When the block gap stop request in the block gap control register is set during ADMA2 operation, the block gap event interrupt will be generated when ADMA2 stops at the block gap. The host controller shall use the Read Wait or Stop SD Clock to stop the ADMA2 read operation. When ADMA2 is stopped, no SD command can be issued. Errors occurred during ADMA2 transfer may stop ADMA2 operation and generate an ADMA error interrupt. The ADMA Error Status field in the ADMA Error Status register stores the status that ADMA2 has stopped. The host driver can identify the location of the error descriptor in two ways. That is, if ADMA stops in the ST_FDS state, the ADMA system address register will point to the error descriptor line. If ADMA stops in the ST_TFR or ST_STOP state, the ADMA system address register will point to the next line of the error descriptor line. Therefore, ADMA2 must not stop in the ST_CADR state.

26.3.13 Test Register

The test register is defined for the purpose of testing. When it is difficult to intentionally generate some interrupts, you may use this function to manually generate such interrupts for driver debugging. To that end, a force event register is defined to control the Error Interrupt Status and the automatic CMD error status. It is also difficult to control card insertion and removal intentionally. The card detection signal selection and card detection test level in the host control 1 register make it possible to manually control the card inserted in the current status register and generate card insertion and card removal interrupts in the Normal Interrupt Status register.

26.3.14 Block Count

The block count command (CMD23) provides an untimed method to stop multi-block operations. The block count is set in the parameter of CMD23 to specify the transfer length of CMD18 or CMD25 after that. Automatic CMD23 is the function of automatically sending CMD23 before sending CMD18 or CMD25. This function aims to avoid performance degradation during memory access by deleting the interrupt service of CMD23. The offset 008h parameter 1 register is used for CMD18 or CMD25. Then an offset of 000h is assigned to the parameter 2 register of CMD23. The host controller does not use the parameter 2 register to calculate the data transfer length. There are two cases of data length of the host-side data transfer operation: non-ADMA and ADMA. The total length of AMDA descriptor refers to the sum of all the 16-bit data length of each ADMA descriptor line. The “block count enable” shall be disabled for ADMA. It is worth noting that the total data transfer length of the host controller shall be equal to the transfer length of the card.

26.3.15 Sampling Clock Tuning

In UHSI mode, the SD bus can run in the high clock frequency mode, and then the data window of cards on CMD and DAT[3:0] lines becomes smaller. The position of the data window varies with the implementation of the card and host system. Hence, when SDR104 or SDR50 is supported by executing the tuning program and adjusting the sampling clock (if the usage tuning of SDR50 is set to 1 in the capability register), the host controller shall support the tuning circuit. The execution tuning and sampling clock selection in the host control 2 register is used to control the tuning circuit.

26.3.16 SD Host Standard Register

26.3.16.1 SD Host Control Register Mapping

The following table summarizes the standard SD host controller register sets. The host driver needs to determine the base address of the register set by the host system specific method. The size of the register set is 256 bytes. For multiple card slot controllers, one register set is assigned to each card slot, but the register at the offset 0F0h0FFh is assigned as a common area, and these registers contain the same value from each card slot register set.

Offset	15-08 bit	07-00 bit	Offset	15-08 bit	07-00 bit
002h	SDMA System Address(High),Argument 2(High)		000h	SDMA System Address(Low),Argument 2(Low)	
006h	Block Count		004h	Block Size

Fig. 26.11: SD Host Control Register Mapping

26.3.16.2 Configuration of Register Type

The configuration register field is assigned an attribute described in the following table:

Register Attribute	Description
RO	Read-only register: Register bits are read-only and cannot be altered by software or any reset operation. Writes to these bits are ignored.
ROC	Read-only status: These bits are initialized to zero at reset. Writes to these bits are ignored.
RW	Read-Write register: Register bits are read-write and may be either set or cleared by software to the desired state.
RW1C	Read-only status, Write-1-to-clear status: Register bits indicate status when read, a set bit indicating a status event may be cleared by writing a 1. Writing a 0 to RW1C bits has no effect.
RWAC	Read-Write, automatic clear register: The Host Driver requests a Host Controller operation by setting the bit. The Host Controllers shall clear the bit automatically when the operation is complete. Writing a 0 to RWAC bits has no effect.
HwInit	Hardware Initialized: Register bits are initialized by firmware or hardware mechanisms such as pin strapping or serial EEPROM. Bits are read-only after initialization, and writes to these bits are ignored.
Rsvd	Reserved. These bits are initialized to zero, and writes to them are ignored.
WO	Write-only register. It is not physically implemented register. Rather, it is an address at which registers can be written.

Fig. 26.12: Types of Registers and Register Bit Fields

26.3.16.3 Initial Value of Register

The host controller sets all registers to their initial values at power-on reset, and the default values of all other registers shall be all bits that are set to zero. The values of the capability register and the maximum current capability register depend on the host controller, and the value of the host controller version register also depends on the host controller.

26.3.16.4 Reserved Bits of a Register

“Reserved” means that this bit can be defined for future use, and it is currently set to 0. These bits shall be set to 0.

Bits	Name	Type	Reset	Description
31:15	RSVD			

Bits	Name	Type	Reset	Description
14:12	HostSDMA	r/w	3'd0	<p>Host SDMA Buffer Boundary</p> <p>The large contiguous memory space may not be available in the virtual memory system. To perform long SDMA transfer, SDMA System Address register shall be updated at every system memory boundary during SDMA transfer.</p> <p>These bits specify the size of contiguous buffer in the system memory. The SDMA transfer shall wait at the every boundary specified by these fields and the Host Controller generates the DMA Interrupt to request the Host Driver to update the SDMA System Address register. At the end of transfer, the Host Controller may issue or may not issue DMA Interrupt. In particular, DMA Interrupt shall not be issued after Transfer Complete Interrupt is issued.</p> <p>In case of this register is set to 0 (buffer size = 4K bytes), lower 12-bit of byte address points data in the contiguous buffer and the upper 20-bit points the location of the buffer in the system memory. The SDMA transfer stops when the Host Controller detects carry out of the address from bit 11 to 12.</p> <p>These bits shall be supported when the SDMA Support in the Capabilities register is set to 1 and this function is active when the DMA Enable in the Transfer Mode register is set to 1. ADMA does not use this register.</p>

Bits	Name	Type	Reset	Description
11:0	TransferBlock	r/w	12'b0	<p>Transfer Block Size</p> <p>This register specifies the block size of data transfers for CMD17, CMD18, CMD24, CMD25, and CMD53. Values ranging from 1 up to the maximum buffer size can be set. In case of memory, it shall be set up to 512 bytes (Refer to Implementation Note in Section 1.7.2). It can be accessed only if no transaction is executing (i.e., after a transaction has stopped). Read operations during transfers may return an invalid value, and write operations shall be ignored.</p>

RSVD Multi / Single Block Select Data Transfer Direction Select Auto CMD Enable Block Count Enable DMA Enable

Bits	Name	Type	Reset	Description
31:6	RSVD			
5	Multi/	r/w	1'b0	<p>Multi / Single Block Select</p> <p>This bit is set when issuing multiple-block transfer commands using DAT line. For any other commands, this bit shall be set to 0. If this bit is 0, it is not necessary to set the Block Count register. (Refer to Table 2-8)</p>
4	DataTransfer	r/w	1'b0	<p>Data Transfer Direction Select</p> <p>This bit defines the direction of DAT line data transfers. The bit is set to 1 by the Host Driver to transfer data from the SD card to the SD Host Controller and it is set to 0 for all other commands.</p>
3:2	AutoCMD	r/w	2'd0	<p>Auto CMD Enable</p> <p>This field determines use of auto command functions.</p> <ul style="list-style-type: none"> (1) Auto CMD12 Enable (2) Auto CMD23 Enable

Bits	Name	Type	Reset	Description
1	BlockCount	r/w	1'b0	This bit is used to enable the Block Count register, which is only relevant for multiple block transfers. When this bit is 0, the Block Count register is disabled, which is useful in executing an infinite transfer. If ADMA2 data transfer is more than 65535 blocks, this bit shall be set to 0. In this case, data transfer length is designated by Descriptor Table.
0	DMAEnable	r/w	1'b0	This bit enables DMA functionality as described in section 1.4. DMA can be enabled only if it is supported as indicated in the Capabilities register. One of the DMA modes can be selected by DMA Select in the Host Control 1 register. If DMA is not supported, this bit is meaningless and shall always read 0. If this bit is set to 1, a DMA operation shall begin when the Host Driver writes to the upper byte of Command register (00Fh).

26.4.6 Command

地址: 0x2006000e

Bits	Name	Type	Reset	Description
31:14	RSVD			

Bits	Name	Type	Reset	Description
13:8	CommandIndex	r/w	6'd0	These bits shall be set to the command number (CMD0-63, ACMD0-63) that is specified in bits 45-40 of the Command-Format in the Physical Layer Specification and SDIO Card Specification.
7:6	CommandType	r/w	2'd0	<p>There are three types of special commands: Suspend, Resume and Abort.</p> <p>These bits shall be set to 00b for all other commands.</p> <p>(1) Suspend Command (2) Resume Command (3) Abort Command</p>
5	DataPresent	r/w	1'b0	<p>This bit is set to 1 to indicate that data is present and shall be transferred using the DAT line. It is set to 0 for the following:</p> <p>(1) Commands using only CMD line (ex. CMD52). (2) Commands with no data transfer but using busy signal on DAT[0] line (R1b or R5b ex. CMD38) (3) Resume command</p>
4	CommandIndex	r/w	1'b0	If this bit is set to 1, the Host Controller shall check the Index field in the response to see if it has the same value as the command index. If it is not, it is reported as a Command Index Error. If this bit is set to 0, the Index field is not checked.
3	CommandCRC	r/w	1'b0	If this bit is set to 1, the Host Controller shall check the CRC field in the response. If an error is detected, it is reported as a Command CRC Error. If this bit is set to 0, the CRC field is not checked. The position of CRC field is determined according to the length of the response. (Refer to definition in D01-00 and Table 2-10 below.)

26.4.12 Present_State

地址: 0x20060024

Bits	Name	Type	Reset	Description
31:25	RSVD			
24	CMDLine	r	1'b0	CMD Line Signal Level This status is used to check the CMD line level to recover from errors, and for debugging.
23:20	DAT[3:0]Line	r	4'd0	DAT[3:0] Line Signal Level This status is used to check the DAT line level to recover from errors, and for debugging. This is especially useful in detecting the busy signal level from DAT[0].
19	WriteProtect	r	1'b0	The Write Protect Switch is supported for memory and combo cards. This bit reflects the SDWP# pin.

Bits	Name	Type	Reset	Description
18	CardDetect	r	1'b0	<p>This bit reflects the inverse value of the SDCD# pin. Debouncing is not performed on this bit. This bit may be valid when Card State Stable is set to 1, but it is not guaranteed because of propagation delay. Use of this bit is limited to testing since it must be debounced by software.</p>
17	CardState	r	1'b0	<p>This bit is used for testing. If it is 0, the Card Detect Pin Level is not stable. If this bit is set to 1, it means the Card Detect Pin Level is stable. No Card state can be detected by this bit is set to 1 and Card Inserted is set to 0. The Software Reset For All in the Software Reset register shall not affect this bit.</p>
16	CardInserted	r	1'b0	<p>This bit indicates whether a card has been inserted. The Host Controller shall debounce this signal so that the Host Driver will not need to wait for it to stabilize. Changing from 0 to 1 generates a Card Insertion interrupt in the Normal Interrupt Status register and changing from 1 to 0 generates a Card Removal interrupt in the Normal Interrupt Status register. The Software Reset For All in the Software Reset register shall not affect this bit. If a card is removed while its power is on and its clock is oscillating, the Host Controller shall clear SD Bus Power in the Power Control register and SD Clock Enable in the Clock Control register. When this bit is changed from 1 to 0, the Host Controller shall immediately stop driving CMD and DAT[3:0] (tri-state). In addition, the Host Driver should clear the Host Controller by the Software. Reset For All in Software Reset register. The card detect is active regardless of the SD Bus Power.</p>
15:12	RSVD			

Bits	Name	Type	Reset	Description
11	BufferRead	roc	1'b0	<p>Buffer Read Enable</p> <p>This status is used for non-DMA read transfers.</p> <p>The Host Controller may implement multiple buffers to transfer data efficiently. This read only flag indicates that valid data exists in the host side buffer. If this bit is 1, readable data exists in the buffer. A change of this bit from 1 to 0 occurs when all the block data is read from the buffer. A change of this bit from 0 to 1 occurs when block data is ready in the buffer and generates the Buffer Read Ready interrupt.</p>
10	BufferWrite	roc	1'b0	<p>Buffer Write Enable</p> <p>This status is used for non-DMA write transfers.</p> <p>The Host Controller can implement multiple buffers to transfer data efficiently. This read only flag indicates if space is available for write data. If this bit is 1, data can be written to the buffer. A change of this bit from 1 to 0 occurs when all the block data is written to the buffer. A change of this bit from 0 to 1 occurs when top of block data can be written to the buffer and generates the Buffer Write Ready interrupt. The Host Controller should neither set Buffer Write Enable nor generate Buffer Write Ready Interrupt after the last block data is written to the Buffer Data Port Register.</p>

Bits	Name	Type	Reset	Description
9	ReadTransfer	roc	1'b0	<p>Read Transfer Active</p> <p>This status is used for detecting completion of a read transfer.</p> <p>This bit is set to 1 for either of the following conditions:</p> <ul style="list-style-type: none"> (1) After the end bit of the read command. (2) When read operation is restarted by writing a 1 to Continue Request in the Block Gap Control register. <p>This bit is cleared to 0 for either of the following conditions::</p> <ul style="list-style-type: none"> (1) When the last data block as specified by block length is transferred to the System. (2) In case of ADMA2, end of read operation is designated by Descriptor Table. (3) When all valid data blocks in the Host Controller have been transferred to the System and no current block transfers are being sent as a result of the Stop At Block Gap Request being set to 1. <p>A Transfer Complete interrupt is generated when this bit changes to 0.</p>

Bits	Name	Type	Reset	Description
8	WriteTransfer	roc	1'b0	<p>Write Transfer Active</p> <p>This status indicates a write transfer is active. If this bit is 0, it means no valid write data exists in the Host Controller. Refer to Section 3.12.4 for more details on the sequence of events.</p> <p>This bit is set in either of the following cases:</p> <ul style="list-style-type: none"> (1) After the end bit of the write command. (2) When write operation is restarted by writing a 1 to Continue Request in the Block Gap Control register. <p>This bit is cleared in either of the following cases:</p> <ul style="list-style-type: none"> (1) After getting the CRC status of the last data block as specified by the transfer count (Single and Multiple) In case of ADMA2, transfer count is designated by Descriptor Table. (2) After getting the CRC status of any block where data transmission is about to be stopped by a Stop At Block Gap Request. <p>During a write transaction, a Block Gap Event interrupt is generated when this bit is changed to 0, as the result of the Stop At Block Gap Request being set. This status is useful for the Host Driver in determining non DAT line commands can be issued during write busy.</p>
7:4	RSVD			

Bits	Name	Type	Reset	Description
3	Re-TuningRequest	roc	1'b0	<p>Re-Tuning Request</p> <p>Host Controller may request Host Driver to execute re-tuning sequence by setting this bit when the data window is shifted by temperature drift and a tuned sampling point does not have a good margin to receive correct data.</p> <p>This bit is cleared when a command is issued with setting Execute Tuning in the Host Control 2 register.</p> <p>Changing of this bit from 0 to 1 generates Re-Tuning Event. Refer to Normal Interrupt Status registers for more detail.</p> <p>This bit isn't set to 1 if Sampling Clock Select in the Host Control 2 register is set to 0 (using fixed sampling clock). Refer to Re-Tuning Modes in the Capabilities register for more detail.</p>
2	DATLine	roc	1'b0	<p>DAT Line Active</p> <p>This bit indicates whether one of the DAT line on SD Bus is in use.</p>
1	CommandInhibit	roc	1'b0	<p>This status bit is generated if either the DAT Line Active or the Read Transfer Active is set to 1. If this bit is 0, it indicates the Host Controller can issue the next SD Command. Commands with busy signal belong to Command Inhibit (DAT) (ex. R1b, R5b type). Changing from 1 to 0 generates a Transfer Complete interrupt in the Normal Interrupt Status register.</p> <p>Note: The SD Host Driver can save registers in the range of 000-00Dh for a suspend transaction after this bit has changed from 1 to 0.</p>

Bits	Name	Type	Reset	Description
0	CommandInhibit	roc	1'b0	<p>If this bit is 0, it indicates the CMD line is not in use and the Host Controller can issue a SD Command using the CMD line.</p> <p>This bit is set immediately after the Command register (00Fh) is written. This bit is cleared when the command response is received. Auto CMD12 and Auto CMD23 consist of two responses. In this case, this bit is not cleared by the response of CMD12 or CMD23 but cleared by the response of a read/write command.</p> <p>Status issuing Auto CMD12 is not read from this bit. So if a command is issued during Auto CMD12 operation, Host Controller shall manage to issue two commands: CMD12 and a command set by Command register.</p> <p>Even if the Command Inhibit (DAT) is set to 1, commands using only the CMD line can be issued if this bit is 0. Changing from 1 to 0 generates a Command Complete Interrupt in the Normal Interrupt Status register. If the Host Controller cannot issue the command because of a command conflict error or because of Command Not Issued By Auto CMD12 Error, this bit shall remain 1 and the Command Complete is not set.</p>

If an unsupported voltage is selected, the Host System shall not supply SD Bus voltage.</p> <ul style="list-style-type: none"> 111b 3.3V (Typ.) 110b 3.0V (Typ.) 101b 1.8V (Typ.) 100b -000b Reserved
0	SDBus	r/w	1'b0	<p>SD Bus Power</p> <p>Before setting this bit, the SD Host Driver shall set SD Bus Voltage Select. If the Host Controller detects the No Card state, this bit shall be cleared.</p> <p>If this bit is cleared, the Host Controller shall immediately stop driving CMD and DAT[3:0] (tri-state) and drive SDCLK to low level .</p>

26.4.15 Block_Gap_Control

地址: 0x2006002a

Bits	Name	Type	Reset	Description
31:4	RSVD			
3	InterruptAt	r/w	1'b0	<p>Interrupt At Block Gap</p> <p>This bit is valid only in 4-bit mode of the SDIO card and selects a sample point in the interrupt cycle. Setting to 1 enables interrupt detection at the block gap for a multiple block transfer. Setting to 0 disables interrupt detection during a multiple block transfer. If the SD card cannot signal an interrupt during a multiple block transfer, this bit should be set to 0. When the Host Driver detects an SD card insertion, it shall set this bit according to the CCCR of the SDIO card.</p>

Bits	Name	Type	Reset	Description
2	ReadWait	r/w	1'b0	<p>Read Wait Control</p> <p>The read wait function is optional for SDIO cards. If the card supports read wait,</p> <p>set this bit to enable use of the read wait protocol to stop read data using the DAT[2] line. Otherwise, the Host Controller has to stop the SD Clock to hold read data, which restricts commands generation. When the Host Driver detects an SD card insertion, it shall set this bit according to the CCCR of the SDIO card. If the card does not support read wait, this bit shall never be set to 1 otherwise DAT line conflict may occur. If this bit is set to 0, Suspend/Resume cannot be supported.</p>
1	ContinueRequest	r/w	1'b0	<p>This bit is used to restart a transaction, which was stopped using the Stop At Block Gap Request. To cancel stop at the block gap, set Stop At Block Gap Request to 0 and set this bit 1 to restart the transfer.</p> <p>The Host Controller automatically clears this bit in either of the following cases:</p> <ul style="list-style-type: none"> (1) In the case of a read transaction, the DAT Line Active changes from 0 to 1 as a read transaction restarts. (2) In the case of a write transaction, the Write Transfer Active changes from 0 to 1 as the write transaction restarts. <p>Therefore, it is not necessary for Host Driver to set this bit to 0. If Stop At Block Gap Request is set to 1, any write to this bit is ignored.</p>

Bits	Name	Type	Reset	Description
0	StopAt	r/w	1'b0	<p>This bit is used to stop executing read and write transaction at the next block gap for non-DMA, SDMA and ADMA transfers. The Host Driver shall leave this bit set to 1 until the Transfer Complete is set to 1. Clearing both Stop At Block Gap Request and Continue Request shall not cause the transaction to restart. When Host Controller version is 1.00, the Host Driver can set this bit if the card supports Read Wait Control. When Host Controller version is 2.00 or later, the Host Driver can set this bit regardless of the card supports Read Wait Control. The Host Controller shall stop read transfer by using Read Wait or stopping SD clock. In case of write transfers in which the Host Driver writes data to the Buffer Data Port register, the Host Driver shall set this bit after all block data is written. If this bit is set to 1, the Host Driver shall not write data to Buffer Data Port register. This bit affects Read Transfer Active, Write Transfer Active, DAT Line Active and Command Inhibit (DAT) in the Present State register.</p>

SDCLK Frequency Select Upper Bits of SDCLK Frequency Select Clock Generator Select SD Clock Enable Internal Clock Stable

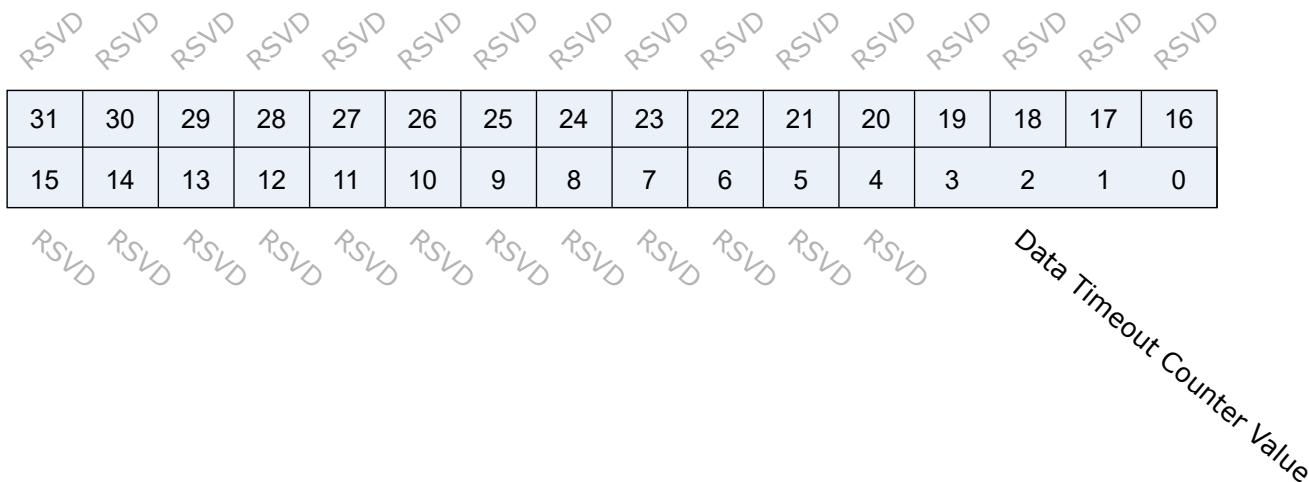

Bits	Name	Type	Reset	Description
31:16	RSVD			
15:8	SDCLKFrequency	r/w	8'd0	<p>SDCLK Frequency Select</p> <p>This register is used to select the frequency of SDCLK pin.</p> <p>The definition of this field is dependent on the Host Controller Version.</p>
7:6	UpperBits	roc/rw	2'd0	<p>Upper Bits of SDCLK Frequency Select</p> <p>Host Controller Version 1.00 and 2.00 do not support these bits and they are treated as 00b fixed value (ROC).</p> <p>Host Controller Version 3.00 shall support these bits to expand SDCLK Frequency Select to 10-bit. Bit 07-06 is assigned to bit 09-08 of clock divider in SDCLK Frequency Select.</p>

Bits	Name	Type	Reset	Description
5	ClockGenerator	roc/rw	1'b0	<p>Clock Generator Select</p> <p>Host Controller Version 3.00 supports this bit. This bit is used to select the clock generator mode in SDCLK Frequency Select.</p> <p>If the Programmable Clock Mode is supported (non-zero value is set to Clock Multiplier in the Capabilities register), this bit attribute is RW, and if not supported, this bit attribute is RO and zero is read.</p> <p>This bit depends on the setting of Preset Value Enable in the Host Control 2 register.</p> <p>If the Preset Value Enable = 0, this bit is set by Host Driver.</p> <p>If the Preset Value Enable = 1, this bit is automatically set to a value specified in one of Preset Value registers.</p> <p>1 Programmable Clock Mode 0 Divided Clock Mode</p>
4:3	RSVD			
2	SDClock	rw	1'b0	<p>SD Clock Enable</p> <p>The Host Controller shall stop SDCLK when writing this bit to 0. SDCLK Frequency Select can be changed when this bit is 0. Then, the Host Controller shall maintain the same clock frequency until SDCLK is stopped (Stop at SDCLK=0). If the Card Inserted in the Present State register is cleared, this bit shall be cleared.</p>
1	InternalClock	roc	1'b0	<p>Internal Clock Stable</p> <p>This bit is set to 1 when SD Clock is stable after writing to Internal Clock</p> <p>Enable in this register to 1. The SD Host Driver shall wait to set SD Clock</p> <p>Enable until this bit is set to 1.</p> <p>Note: This is useful when using PLL for a clock oscillator that requires setup time.</p>

Bits	Name	Type	Reset	Description
0	InternalClock	r/w	1'b0	<p>Internal Clock Enable</p> <p>This bit is set to 0 when the Host Driver is not using the Host Controller or the Host Controller awaits a wakeup interrupt. The Host Controller should stop its internal clock to go very low power state. Still, registers shall be able to be read and written. Clock starts to oscillate when this bit is set to 1. When clock oscillation is stable, the Host Controller shall set Internal Clock Stable in this register to 1. This bit shall not affect card detection.</p>

26.4.18 Timeout_Control

地址: 0x2006002e

Bits	Name	Type	Reset	Description
31:4	RSVD			

Bits	Name	Type	Reset	Description
3:0	DateTimeout	r/w	4'd0	<p>Data Timeout Counter Value</p> <p>This value determines the interval by which DAT line timeouts are detected. For more information about timeout generation, refer to the Data Timeout Error in the Error Interrupt Status register. Timeout clock frequency will be generated by dividing the base clock TMCLK value by this value. When setting this register, prevent inadvertent timeout events by clearing the Data Timeout Error Status Enable (in the Error Interrupt Status Enable register)</p>

Bits	Name	Type	Reset	Description
1	SoftwareReset	rwac	1'b0	<p>Software Reset For CMD Line</p> <p>Only part of command circuit is reset.</p> <p>The following registers and bits are cleared by this bit:</p> <ul style="list-style-type: none"> Present State register Command Inhibit (CMD) Normal Interrupt Status register Command Complete
0	SoftwareReset	rwac	1'b0	<p>Software Reset For All</p> <p>This reset affects the entire Host Controller except for the card detection circuit.</p> <p>Register bits of type ROC, RW, RW1C, RWAC are cleared to 0. During its initialization, the Host Driver shall set this bit to 1 to reset the Host Controller. The Host Controller shall reset this bit to 0 when Capabilities registers are valid and the Host Driver can read them. Additional use of Software Reset For All may not affect the value of the Capabilities registers. If this bit is set to 1, the host driver should issue reset command and reinitialize the SD card.</p>

26.4.20 Normal Interrupt Status

地址: 0x20060030

Bits	Name	Type	Reset	Description
31:16	RSVD			

Bits	Name	Type	Reset	Description
15	ErrorInterrupt	roc	1'b0	<p>Error Interrupt</p> <p>If any of the bits in the Error Interrupt Status register are set, then this bit is set. Therefore the Host Driver can efficiently test for an error by checking this bit first. This bit is read only.</p>
14:13	RSVD			
12	Re-TuningEvent	roc	1'b0	<p>Re-Tuning Event</p> <p>This status is set if Re-Tuning Request in the Present State register changes from 0 to 1.</p> <p>Host Controller requests Host Driver to perform re-tuning for next data transfer. Current data transfer (not large block count) can be completed without re-tuning.</p>
11	INT_C	roc	1'b0	<p>INT_C</p> <p>This status is set if INT_C is enabled and INT_C# pin is in low level. Writing this bit to 1 does not clear this bit. It is cleared by resetting the INT_C interrupt factor. Refer to the Shared Bus Control register.</p>
10	INT_B	roc	1'b0	<p>INT_B</p> <p>This status is set if INT_B is enabled and INT_B# pin is in low level. Writing this bit to 1 does not clear this bit. It is cleared by resetting the INT_B interrupt factor. Refer to the Shared Bus Control register.</p>
9	INT_A	roc	1'b0	<p>INT_A</p> <p>This status is set if INT_A is enabled and INT_A# pin is in low level. Writing this bit to 1 does not clear this bit. It is cleared by resetting the INT_A interrupt factor. Refer to the Shared Bus Control register.</p>

Bits	Name	Type	Reset	Description
8	CardInterrupt	roc	1'b0	<p>Card Interrupt</p> <p>Writing this bit to 1 does not clear this bit. It is cleared by resetting the SD card interrupt factor. In 1-bit mode, the Host Controller shall detect the Card</p> <p>Interrupt without SD Clock to support wakeup. In 4-bit mode, the card interrupt signal is sampled during the interrupt cycle, so there are some sample delays between the interrupt signal from the SD card and the interrupt to the Host System.</p> <p>When this status has been set and the Host Driver needs to start this interrupt service, Card Interrupt Status Enable in the Normal Interrupt</p> <p>Status Enable register may be set to 0 in order to clear the card interrupt statuses latched in the Host Controller and to stop driving the interrupt signal to the Host System. After completion of the card interrupt service (It should reset interrupt factors in the SD card and the interrupt signal may not be asserted), set Card Interrupt Status Enable to 1 and start sampling the interrupt signal again.</p> <p>Interrupt detected by DAT[1] is supported when there is a card per slot. In case of shared bus, interrupt pins are used to detect interrupts. If 000b is set to Interrupt Pin Select in the Shared Bus Control register, this status is effective. Non-zero value is set to Interrupt Pin Select, INT_A, INT_B or INT_C is then used to device interrupts.</p>

Bits	Name	Type	Reset	Description
7	CardRemoval	rw1c	1'b0	<p>Card Removal</p> <p>This status is set if the Card Inserted in the Present State register changes from 1 to 0.</p> <p>When the Host Driver writes this bit to 1 to clear this status, the status of the Card Inserted in the Present State register should be confirmed. Because the card detect state may possibly be changed when the Host Driver clear this bit and interrupt event may not be generated.</p>
6	CardInsertion	rw1c	1'b0	<p>Card Insertion</p> <p>This status is set if the Card Inserted in the Present State register changes from 0 to 1.</p> <p>When the Host Driver writes this bit to 1 to clear this status, the status of the Card Inserted in the Present State register should be confirmed. Because the card detect state may possibly be changed when the Host Driver clear this bit and interrupt event may not be generated.</p>
5	BufferRead	rw1c	1'b0	<p>Buffer Read Ready</p> <p>This status is set if the Buffer Read Enable changes from 0 to 1. Refer to the Buffer Read Enable in the Present State register. While performing tuning procedure (Execute Tuning is set to 1), Buffer Read Ready is set to 1 for every CMD19 execution.</p>
4	BufferWrite	rw1c	1'b0	<p>Buffer Write Ready</p> <p>This status is set if the Buffer Write Enable changes from 0 to 1. Refer to the Buffer Write Enable in the Present State register.</p>

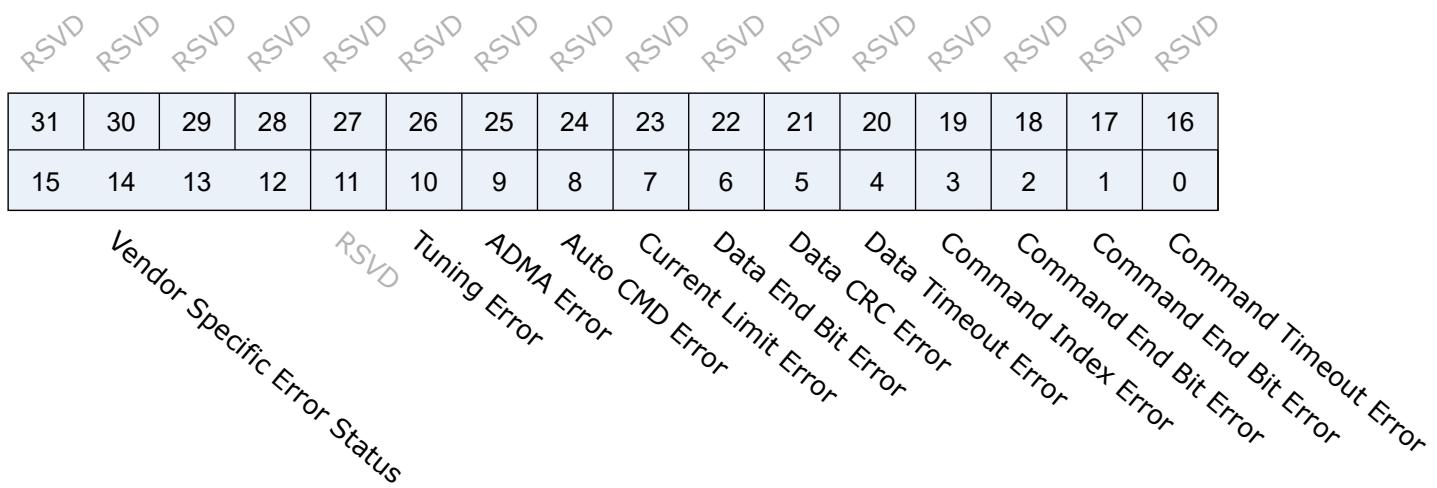

Bits	Name	Type	Reset	Description
3	DMAInterrupt	rw1c	1'b0	<p>DMA Interrupt</p> <p>This status is set if the Host Controller detects the Host SDMA Buffer boundary during transfer. Refer to the Host SDMA Buffer Boundary in the Block Size register.</p> <p>Other DMA interrupt factors may be added in the future.</p> <p>In case of ADMA, by setting Int field in the descriptor table, Host Controller generates this interrupt. Suppose that it is used for debugging.</p> <p>This interrupt shall not be generated after the Transfer Complete.</p>
2	BlockGap	rw1c	1'b0	<p>Block Gap Event</p> <p>If the Stop At Block Gap Request in the Block Gap Control register is set,</p> <p>this bit is set when both a read / write transaction is stopped at a block gap.</p> <p>If Stop At Block Gap Request is not set to 1, this bit is not set to 1.</p> <p>(1) In the case of a Read Transaction</p> <p>This bit is set at the falling edge of the DAT Line Active Status (When the transaction is stopped at SD Bus timing. The Read Wait shall be supported in order to use this function. Refer to Section 3.12.3 about the detail timing.</p> <p>(2) Case of Write Transaction</p> <p>This bit is set at the falling edge of Write Transfer Active Status (After getting CRC status at SD Bus timing). Refer to Section 3.12.4 for more details on the sequence of events.</p>

Bits	Name	Type	Reset	Description
1	TransferComplete	rw1c	1'b0	<p>Transfer Complete</p> <p>This bit is set when a read / write transfer and a command with busy is completed.</p> <p>(1) In the case of a Read Transaction</p> <p>This bit is set at the falling edge of Read Transfer Active Status.</p> <p>This interrupt is generated in two cases. The first is when a data transfer is completed as specified by data length (After the last data has been read to the Host System). The second is when data has stopped at the block gap and completed the data transfer by setting the Stop At Block Gap Request in the Block Gap Control register (After valid data has been read to the Host System).</p> <p>(2) In the case of a Write Transaction</p> <p>This bit is set at the falling edge of the DAT Line Active Status. This interrupt is generated in two cases. The first is when the last data is written to the SD card as specified by data length and the busy signal released. The second is when data transfers are stopped at the block gap by setting Stop At Block Gap Request in the Block Gap Control register and data transfers completed. (After valid data is written to the SD card and the busy signal released).</p> <p>(3) In the case of a command with busy</p> <p>This bit is set when busy is de-asserted. Refer to DAT Line Active and Command Inhibit (DAT) in the Present State register.</p>

Bits	Name	Type	Reset	Description
0	CommandComplete	rw1c	1'b0	<p>Command Complete</p> <p>This bit is set when get the end bit of the command response. Auto CMD12 and Auto CMD23 consist of two responses. Command Complete is not generated by the response of CMD12 or CMD23 but generated by the response of a read/write command.</p> <p>Refer to Command Inhibit (CMD) in the Present State register for how to control this bit.</p> <p>The table below shows that Command Timeout Error has higher priority than Command Complete. If both bits are set to 1, it can be considered that the response was not received correctly.</p>

26.4.21 Error_Interrupt_Status

地址: 0x20060032

Bits	Name	Type	Reset	Description
31:16	RSVD			
15:12	VendorSpecific	rw1c	4'd0	<p>Vendor Specific Error Status</p> <p>Additional status bits can be defined in this register by the vendor.</p>
11	RSVD			

Bits	Name	Type	Reset	Description
10	TuningError	rw1c	1'b0	<p>Tuning Error</p> <p>This bit is set when an unrecoverable error is detected in a tuning circuit</p> <p>except during tuning procedure (Occurrence of an error during tuning</p> <p>procedure is indicated by Sampling Select). By detecting Tuning Error, Host</p> <p>Driver needs to abort a command executing and perform tuning. To reset</p> <p>tuning circuit, Sampling Clock shall be set to 0 before executing tuning</p> <p>procedure . The Tuning Error is higher priority than the other error interrupts generated during data transfer. By detecting Tuning</p> <p>Error, the Host Driver should discard data transferred by a current read/write</p> <p>command and retry data transfer after the Host Controller retrieved from</p> <p>tuning circuit error.</p>
9	ADMAError	rw1c	1'b0	<p>ADMA Error</p> <p>This bit is set when the Host Controller detects errors during ADMA based data</p> <p>transfer. The state of the ADMA at an error occurrence is saved in the ADMA</p> <p>Error Status Register,</p> <p>In addition, the Host Controller generates this Interrupt when it detects invalid</p> <p>descriptor data (Valid=0) at the ST_FDS state. ADMA Error State in the</p> <p>ADMA Error Status indicates that an error occurs in ST_FDS state. The Host</p> <p>Driver may find that Valid bit is not set at the error descriptor.</p>

Bits	Name	Type	Reset	Description
8	AutoCMD	rw1c	1'b0	<p>Auto CMD Error</p> <p>Auto CMD12 and Auto CMD23 use this error status. This bit is set when detecting that one of the bits D00-D04 in Auto CMD Error Status register has changed from 0 to 1. In case of Auto CMD12, this bit is set to 1, not only when the errors in Auto CMD12 occur but also when Auto CMD12 is not executed due to the previous command error.</p>
7	CurrentLimit	rw1c	1'b0	<p>Current Limit Error</p> <p>By setting the SD Bus Power bit in the Power Control register, the Host Controller is requested to supply power for the SD Bus. If the Host Controller supports the Current Limit function, it can be protected from an illegal card by stopping power supply to the card in which case this bit indicates a failure status. Reading 1 means the Host Controller is not supplying power to SD card due to some failure. Reading 0 means that the Host Controller is supplying power and no error has occurred. The Host Controller may require some sampling time to detect the current limit. If the Host Controller does not support this function, this bit shall always be set to 0.</p>
6	DataEnd	rw1c	1'b0	<p>Data End Bit Error</p> <p>Occurs either when detecting 0 at the end bit position of read data which uses the DAT line or at the end bit position of the CRC Status.</p>
5	DataCRC	rw1c	1'b0	<p>Data CRC Error</p> <p>Occurs when detecting CRC error when transferring read data which uses the DAT line or when detecting the Write CRC status having a value of other than "010".</p>

Bits	Name	Type	Reset	Description
4	DateTimeout	rw1c	1'b0	<p>Data Timeout Error</p> <p>This bit is set when detecting one of following timeout conditions.</p> <ul style="list-style-type: none"> (1) Busy timeout for R1b,R5b type (2) Busy timeout after Write CRC status (3) Write CRC Status timeout (4) Read Data timeout.
3	CommandIndex	rw1c	1'b0	<p>Command Index Error</p> <p>This bit is set if a Command Index error occurs in the command response.</p>
2	CommandEnd	rw1c	1'b0	<p>Command End Bit Error</p> <p>This bit is set when detecting that the end bit of a command response is 0.</p>
1	CommandEnd	rw1c	1'b0	<p>Command CRC Error</p> <p>Command CRC Error is generated in two cases.</p> <p>If a response is returned and the Command Timeout Error is set to 0 (indicating no timeout), this bit is set to 1 when detecting a CRC error in the command response.</p> <p>The Host Controller detects a CMD line conflict by monitoring the CMD line when a command is issued. If the Host Controller drives the CMD line to 1 level, but detects 0 level on the CMD line at the next SD clock edge, then the Host Controller shall abort the command (Stop driving CMD line) and set this bit to 1. The Command Timeout Error shall also be set to 1 to distinguish CMD line conflict .</p>
0	CommandTimeout	rw1c	1'b0	<p>Command Timeout Error</p> <p>This bit is set only if no response is returned within 64 SD clock cycles from the end bit of the command.</p>

Preset Value Enable Asynchronous Interrupt Enable RSVD RSVD RSVD RSVD RSVD RSVD Sampling Clock Select Execute Tuning Driver Strength Select 1.8V Signaling Enable UHS Mode Select

Bits	Name	Type	Reset	Description
31:16	RSVD			
15	PresetValue	r/w	1'b0	<p>Preset Value Enable</p> <p>Host Controller Version 3.00 supports this bit.</p> <p>As the operating SDCLK frequency and I/O driver strength depend on the Host System implementation, it is difficult to determine these parameters in the Standard Host Driver. When Preset Value Enable is set, automatic SDCLK frequency generation and driver strength selection is performed without considering system specific conditions. This bit enables the functions defined in the Preset Value registers.</p>

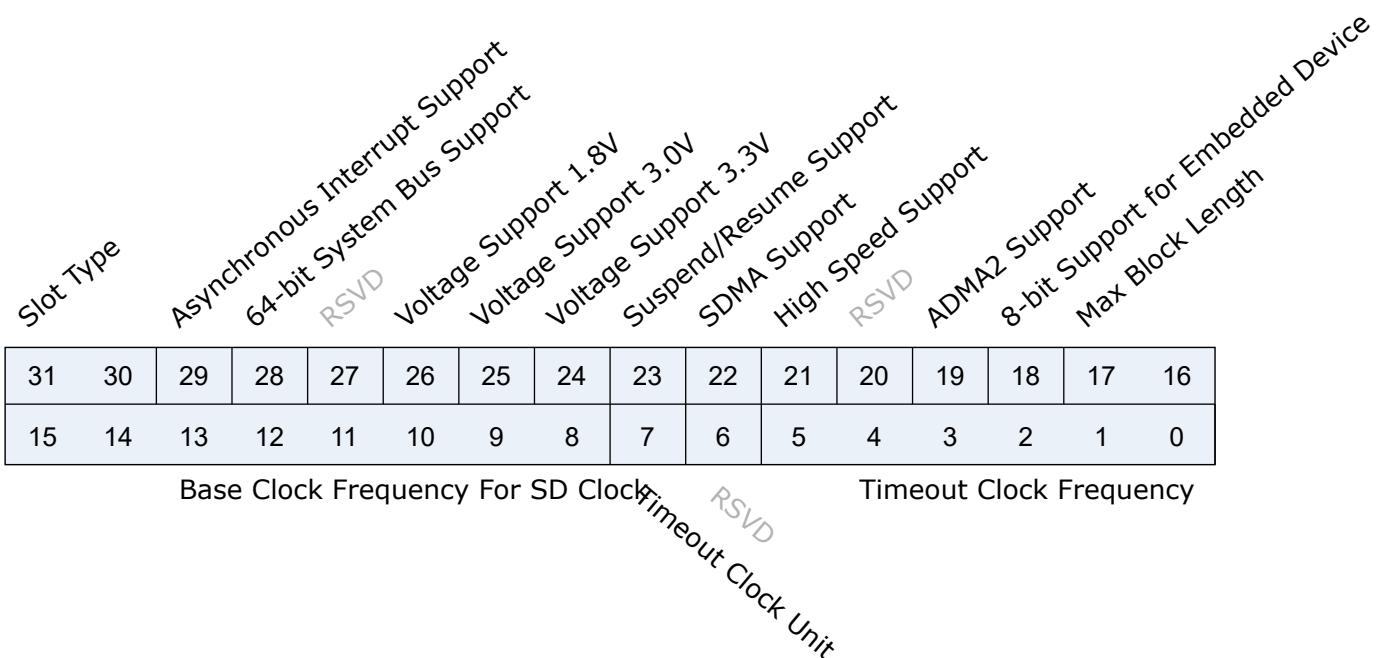

Bits	Name	Type	Reset	Description
14	AsynchronousInterrupt	r/w	1'b0	<p>Asynchronous Interrupt Enable</p> <p>This bit can be set to 1 if a card supports asynchronous interrupts and</p> <p>Asynchronous Interrupt Support is set to 1 in the Capabilities register.</p> <p>Asynchronous interrupt is effective when DAT[1] interrupt is used in 4-bit SD mode (and zero is set to Interrupt Pin Select in the Shared Bus Control register). If this bit is set to 1, the Host Driver can stop the SDCLK during asynchronous interrupt period to save power. During this period, the Host Controller continues to deliver the Card Interrupt to the host when it is asserted by the Card.</p>
13:8	RSVD			
7	SamplingClock	r/w	1'b0	<p>Sampling Clock Select</p> <p>Host Controller uses this bit to select sampling clock to receive CMD and DAT. This bit is set by tuning procedure and valid after the completion of tuning (when Execute Tuning is cleared). Setting 1 means that tuning is completed successfully and setting 0 means that tuning is failed. Writing 1 to this bit is meaningless and ignored. A tuning circuit is reset by writing to 0.</p> <p>This bit can be cleared with setting Execute Tuning. Once the tuning circuit is reset, it will take time to complete tuning sequence. Therefore, Host Driver should keep this bit to 1 to perform re-tuning sequence to compete re-tuning sequence in a short time. Change of this bit is not allowed while the Host Controller is receiving response or a read data block.</p>

Bits	Name	Type	Reset	Description
6	ExecuteTuning	rwac	1'b0	<p>Execute Tuning</p> <p>This bit is set to 1 to start tuning procedure and automatically cleared when tuning procedure is completed. The result of tuning is indicated to Sampling</p> <p>Clock Select. Tuning procedure is aborted by writing 0. Refer to Figure 2-29 for more detail about tuning procedure.</p>
5:4	DriverStrength	r/w	2'd0	<p>Driver Strength Select</p> <p>Host Controller output driver in 1.8V signaling is selected by this bit. In 3.3V signaling, this field is not effective. This field can be set depends on Driver</p> <p>Type A, C and D support bits in the Capabilities register. This bit depends on setting of Preset Value Enable.</p> <p>If Preset Value Enable = 0, this field is set by Host Driver.</p> <p>If Preset Value Enable = 1, this field is automatically set by a value specified in the one of Preset Value registers.</p>
3	1.8VSignaling	r/w	1'b0	<p>1.8V Signaling Enable</p> <p>This bit controls voltage regulator for I/O cell. 3.3V is supplied to the card regardless of signaling voltage.</p> <p>Setting this bit from 0 to 1 starts changing signal voltage from 3.3V to 1.8V.</p> <p>1.8V regulator output shall be stable within 5ms. Host Controller clears this bit if switching to 1.8V signaling fails.</p> <p>Clearing this bit from 1 to 0 starts changing signal voltage from 1.8V to 3.3V.</p> <p>3.3V regulator output shall be stable within 5ms.</p> <p>Host Driver can set this bit to 1 when Host Controller supports 1.8V signaling</p> <p>(One of support bits is set to 1: SDR50, SDR104 or DDR50 in the Capabilities register) and the card or device supports UHS-I (S18A=1. Refer to Bus Signal Voltage Switch Sequence in the Physical Layer Specification Version 3.0x).</p>

Bits	Name	Type	Reset	Description
2:0	UHSMode	r/w	3'd0	UHS Mode Select This field is used to select one of UHS-I modes and effective when 1.8V Signaling Enable is set to 1.

27.1 Overview

ISO11898, an international standard, is one of the most widely used fieldbus in the industrial and automotive fields.

27.2 Features

- Custom bit rate
- ISO11898 2.0A and 2.0B
- Self-test mode (self-sending and self-receiving)
- Frame filtering
- Silent mode (no reply, no valid error flag)
- Single transmission without retransmission
- Query of bits that lose the arbitration
- Any bus error can trigger an interrupt

27.3 Functional Description

27.3.1 TX Buffer (TXB)

TXB, an interface between CPU and BSP, can store complete messages for transmission over the ISO11898 network. The buffer length is 13 bytes, written by CPU and read by the BSP.

27.3.2 RX Buffer (RXB, RXFIFO)

RXB, an interface between access control filter and CPU, is used to store the filtered messages received from the ISO11898 bus. RXB represents a 13-byte window in the RX FIFO that can be accessed by CPU, with a total length of 64 bytes. RX FIFO allows CPU to receive other messages while processing one frame of message.

27.3.3 Access Control Filter (ACF)

ACF compares the received identifier with the contents of the ACF register and decides whether the message should be accepted. If accepted, the complete message will be stored in RX FIFO.

27.3.4 Bit Stream Processor (BSP)

BSP, a sequence generator, is used to process the data between TXB, RXB, and ISO11898 bus. It also performs error detection, arbitration, bit padding, and error handling on the ISO11898 bus.

27.3.5 Bit Timing Logic (BTL)

BTL monitors the serial ISO11898 bus and processes the bus related bit timing. It performs hard synchronization on the recessive-to-dominant transition of the bus at the beginning of the message, and soft synchronization again during subsequent message reception. BTL also provides a programmable time period to compensate propagation delay and phase shift (for example, due to oscillator drift), and can define sampling points and sampling times in a bit time.

27.3.6 Error Management Logic (EML)

EML determines the errors of the transport layer module. It receives the error statement from BSP and then informs BSP and interrupt management logic (IML) of error statistics.

27.4 Functional Description

27.4.1 Mode

27.4.1.1 Self-test Mode

You can select the self-test mode by setting the STM bit in the MOD register to ‘1’ . In this mode, the RX request command can be used to conduct a full-node test without other active nodes on the bus, and even if no response is received, the ISO11898 controller will perform successful transmission.

27.4.1.2 Silent Mode

You can select the silent mode by setting the LOM bit in the MOD register to “1”. In this mode, the ISO11898 controller will not respond to the ISO11898 bus even if it successfully receives the message, and the error counter will stay at the current value. This mode will force the ISO11898 controller to become a passive error, and no message can be transmitted at this time. This mode can be used in software-driven bit rate detection and hot swap scenarios, and all other functions work normally as the normal mode.

27.4.1.3 Reset Mode

Once the RM bit in the MOD register changes from ‘0’ to ‘1’, it will cause the current TX and RX messages to be terminated and enter the reset mode. When the RM bit changes from ‘1’ to ‘0’, the ISO11898 controller will return to the operating mode.

The meanings of different operations in different modes are as follows.

Table 27.1: The meaning of each register in different modes

ADDRESS OFFSET	OPERATING MODE		RESET MODE	
	READ	WRITE	READ	WRITE
0x00	mode	mode	mode	mode
0x04	(00H)	command	(00H)	command

0x7C	clock divider		clock divider		clock divider	clock divider

27.4.2 Sending Process

27.4.2.1 Process

1. Check the TBS bit in the SR register to ensure that TXB is empty.
2. Configure frame information, ID number, and data.
3. Request transmission by setting the TR bit in the CMR register.

27.4.2.2 Termination of Sending

When CPU requests to suspend the previous transmission, you can use this function. For example, you need to send a more urgent message first. Messages that are sending now are not affected by this function and sending will not stop. To check whether the previous message was successfully sent, you should check the TCS bit in the SR register. The application software can use this function by setting the AT bit in the CMR register to ‘1’ , which should be executed after the TBS bit in the SR register is set to ‘1’ or the TX interrupt is generated.

It should be noted that even if the message is terminated, a TX interrupt will occur, because the status bit of the TXB has indicated the “released” status.

27.4.2.3 Self-sending and Self-receiving

The application software can realize self-sending and self-receiving by setting the SRR bit in the CMR register. At that time, sending and receiving are synchronized. Other operations are the same as the normal sending process.

27.4.2.4 Precautions

1. If the TR and AT bits of the CMA register are set simultaneously, the message will be sent only once. Even if there is an error event or arbitration lost, it will not be sent again.
2. If the SRR and AT bits of the CMA register are set simultaneously, the message will be sent only once by self-sending and self-receiving. Even if there is an error event or arbitration lost, it will not be sent again.
3. If SRR, TR, and AT bits of the CMA register are set simultaneously, the message will be sent by setting TR and AT bits simultaneously.
4. Once the TX status bit in the status register is set, the internal TX request bit will be cleared automatically.
5. If the TR and SRR bits of the CMA register are set simultaneously, the SRR bit will be ignored.

27.4.3 Receiving Process

27.4.3.1 Process

The received messages are stored in an internal FIFO with a depth of 64 bytes. The FIFO is completely managed by hardware, which saves CPU’s processing load, simplifies software, and ensures data consistency. The application can read the received messages through the FIFO’s output interface. When the RBS bit in the SR register is set, one or more frames of messages can be read in RX FIFO. After the software gets the message, setting the RRB bit in the CMR register can release the RX FIFO occupied by the current message.

27.4.3.2 Number of Messages

The RMC register indicates the number of readable messages in RX FIFO, which increases with each RX event and decreases with each buffer release. The value is 0 after reset.

27.4.3.3 RXB

The RBSA register indicates the address of the first byte of the received message stored in the current internal RAM, which is mapped to the RXB window. The contents of the internal RAM can be interpreted on this basis. This part of the internal RAM can be read and written by CPU (written only in the reset mode).

Example: If the value of RBSA is 18H, the current readable message of the RXB window (offset address: 10H to 12H) is also stored in the RAM address starting from 18H. As the RAM address is directly mapped to the starting position of ISO11898 offset address 20H (corresponding to RAM address 0H), the message can also be read from ISO11898 offset address 38H and the following bytes (ISO11898 address = RBSA + 20H = 18H + 20H = 38H). If the message address exceeds the RAM address 3FH, it will continue from the RAM address 0.

When there is at least one message in FIFO, the command to release the RXB should be issued, and then RBSA will be updated to the starting position of the next message.

When the hardware is reset, the value of RBSA register is initialized to ‘00H’ . When the software is reset in the reset mode, the value of this register will not change, but the FIFO will be cleared. This means that the contents of RAM will not change, but the next received (or sent) message will overwrite the visible message in the RXB window.

27.4.4 Identifier Filtering

With the help of ACF, the ISO11898 controller will allow the received message to be delivered to RX FIFO only when the identifier bit of the received message is the same as the predefined bit in the ACF register. ACF consists of the acceptance code registers (ACRn) and acceptance mask registers (AMRn). The values of matching bits in the receivable message are set by the ACRn, and which bits can be masked is set by the AMRn.

There are two different filtering modes (set by the AFM bit in the MOD register):

- Single filter mode (AFM = 1).
- Double filter mode (AFM = 0).

27.4.4.1 Single Filter Configuration

In this configuration, a 4-byte long filter can be defined. The bit correspondence between filter bytes and message bytes depends on the currently received frame format.

Standard frame: If a message in a standard frame format is received, the complete identifier including the RTR bit and the first two data bytes is used to accept filtering. If there is no data byte because RTR bit is set, or there is no data byte or only one data byte because a data length is set, the message can also be received.

As all the filter bits are logically AND, only when all the bits pass through the filter, can a message be received. It should be noted that the low 4 bits of AMR1 and ACR1 are unused, and these bits should be set as mask bits for compatibility with future products. That is, all 3-0 bits of AMR1 are ‘1’ .

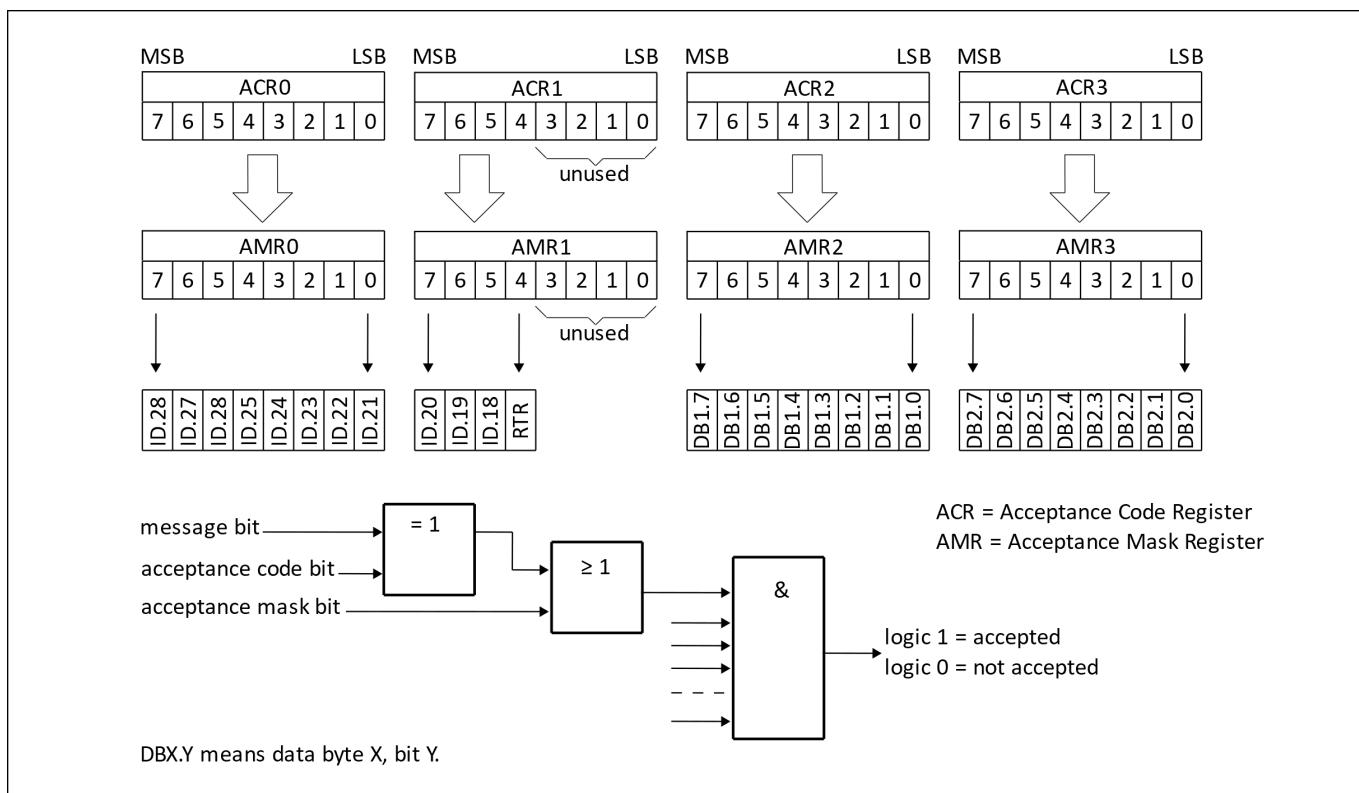

Fig. 27.1: Single filter configuration, receiving standard frame messages

Extended frame: If a message in an extended frame format is received, the complete identifier including the RTR bit is used to accept filtering.

As all the filter bits are logically AND, only when all the bits pass through the filter, can a message be received. It should be noted that the low 2 bits of AMR3 and ACR3 are unused, and these bits should be set as mask bits for compatibility with future products. That is, all 1-0 bits of AMR3 are ‘1’ .

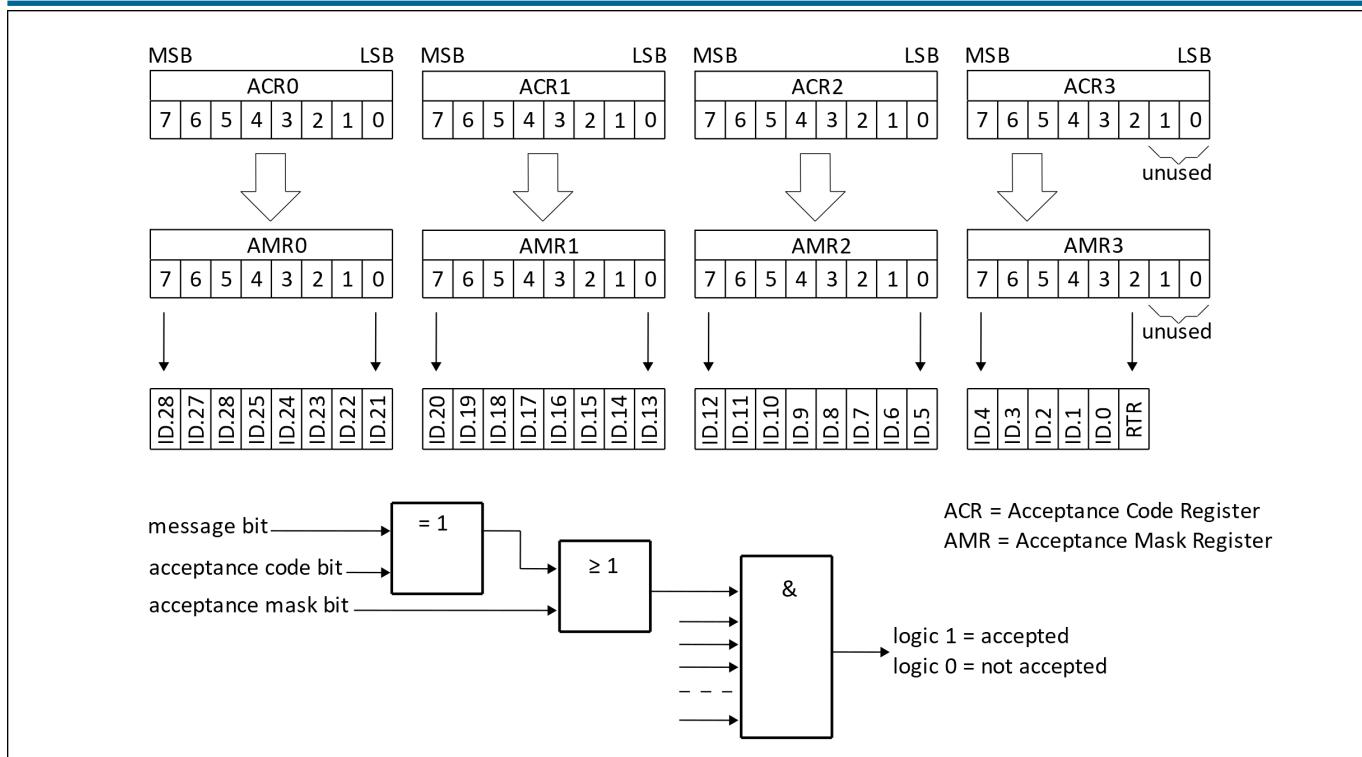

Fig. 27.2: Single filter configuration, receiving extended frame messages

27.4.4.2 Double Filter Configuration

Two short filters can be defined in this configuration, and the received message will be compared with both filters to decide whether to copy the message to the RXB. As long as a filter receives the message, the received message is valid. The bit correspondence between filter bytes and message bytes depends on the currently received frame format.

Standard frame: If a message in a standard frame format is received, the two filters defined look a little different. The first filter compares the complete identifier including RTR and the first data byte, while the second one only compares the standard identifier including RTR.

To successfully receive the message, the comparison result of all single bits in at least one complete filter indicates “accept”. There is no data when RTR is set or the data length is 0. However, if the first part up to the RTR bit indicates “accept”, the message can also pass through the filter 1.

If the first filter does not need to filter data bytes, the low 4 bits of AMR1 and AMR3 must be set to logical ‘1’ (insignificant), and the two filters run identically using standard identifiers including RTR.

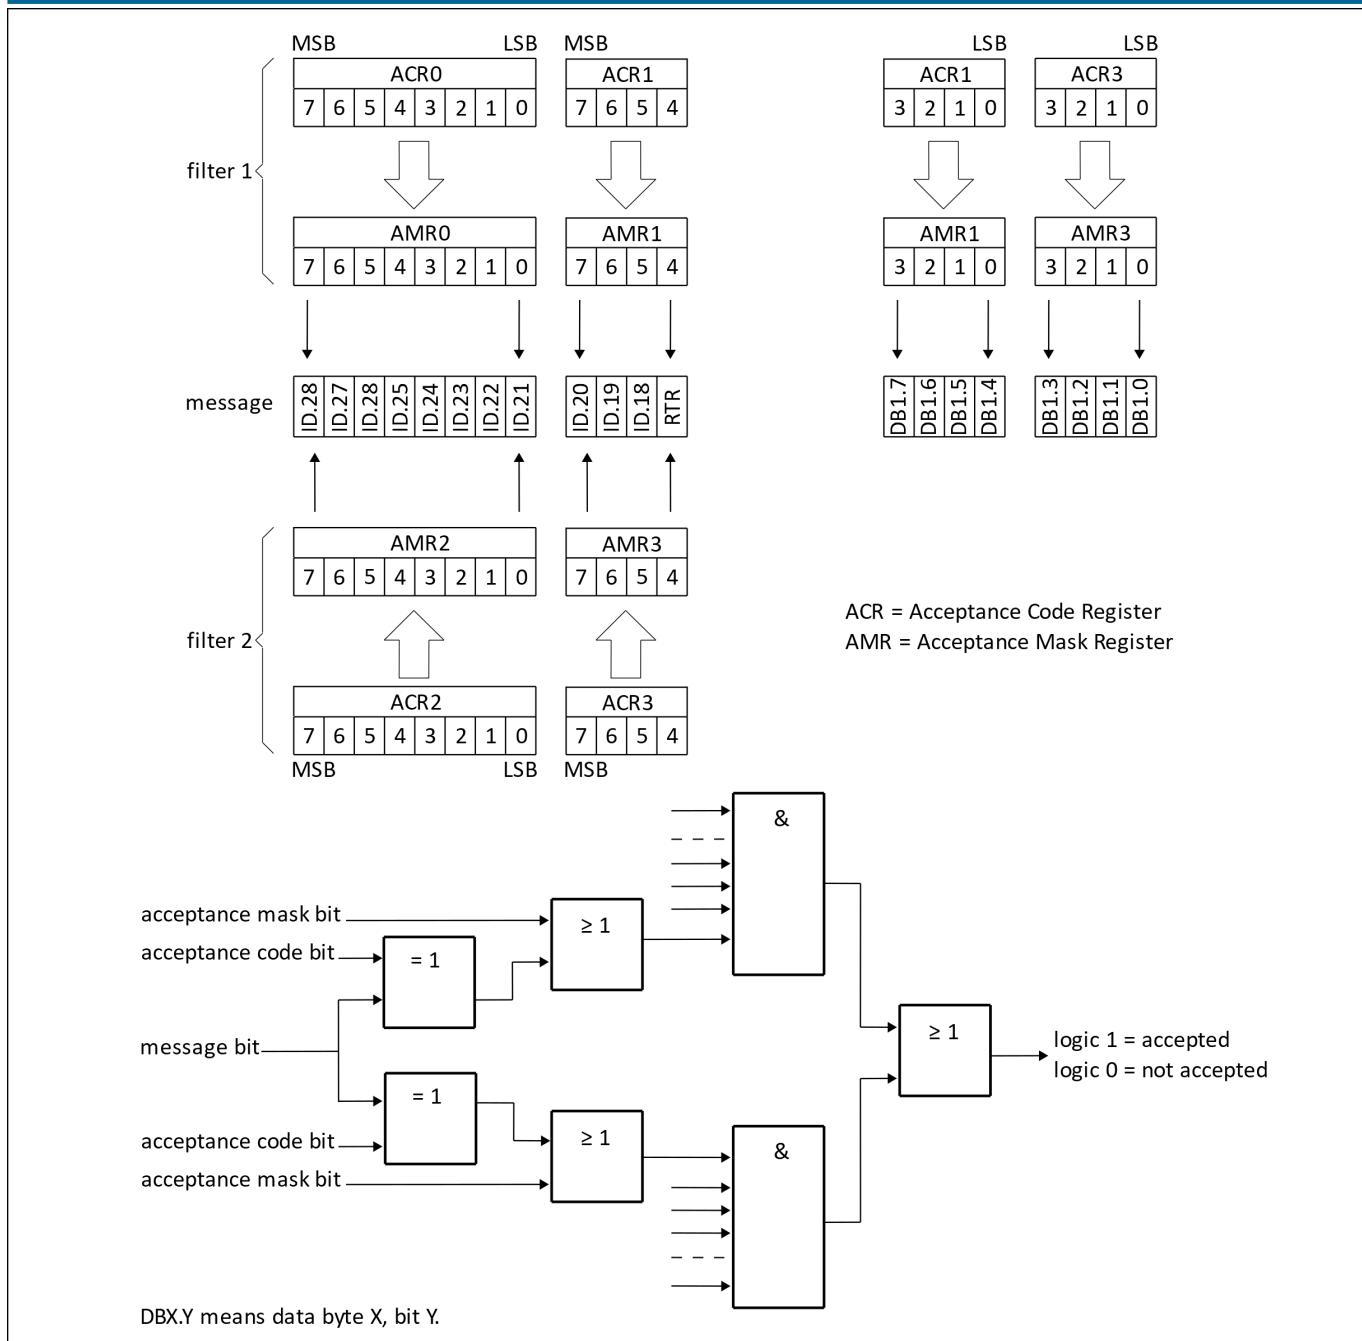

Fig. 27.3: Dual filter configuration, receiving standard frame messages

Extended frame: If a message in an extended frame format is received, the two filters defined look the same. Both filters only compare the first two bytes of the extended identifier.

Only when all single bit comparisons of at least one complete filter indicate acceptance, can the message be successfully received.

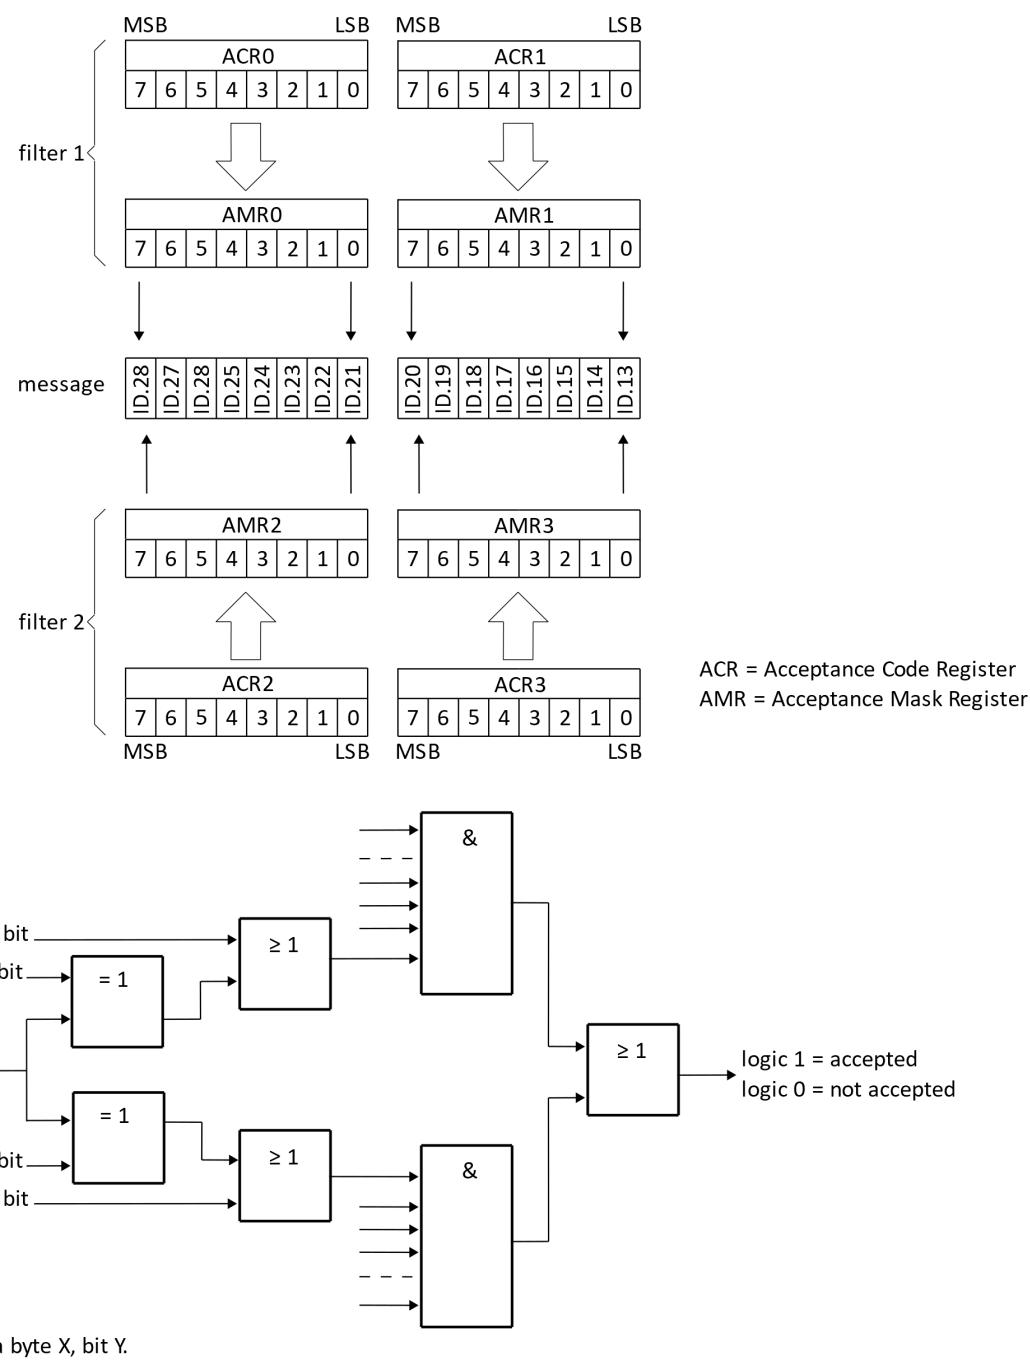

Fig. 27.4: Dual filter configuration, receiving extended frame messages

27.4.5 Error Management

27.4.5.1 Arbitration Lost

The arbitration lost capture (ALC) register contains the position that encounters arbitration lost and can only be read by CPU but not written by it. If the arbitration lost interrupt is enabled, an interrupt will be generated once arbitration loses. The position of the current bit in BSP is captured into the ALC. This register's value is fixed until the user software reads the contents of the ALC. After this value is read, the capture mechanism is activated again. When the interrupt register is read, the corresponding interrupt flag will also be cleared. No arbitration lost interrupt will be generated again before the ALC register is read.

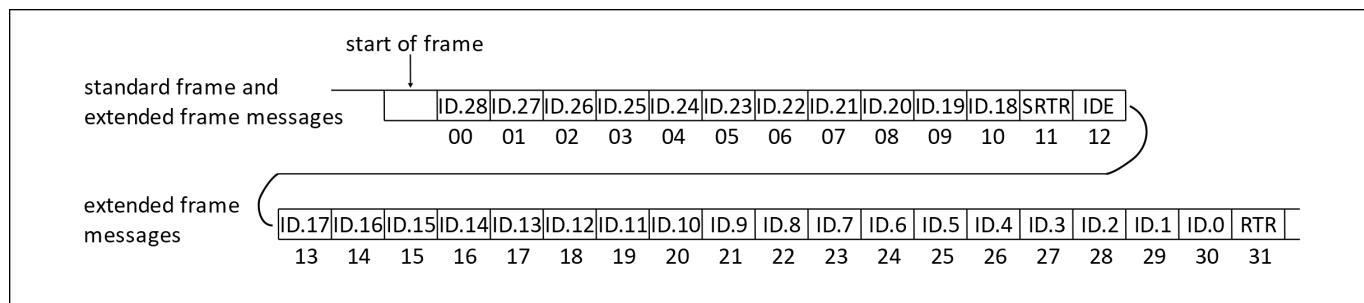

Fig. 27.5: Arbitration lost bit number interpretation

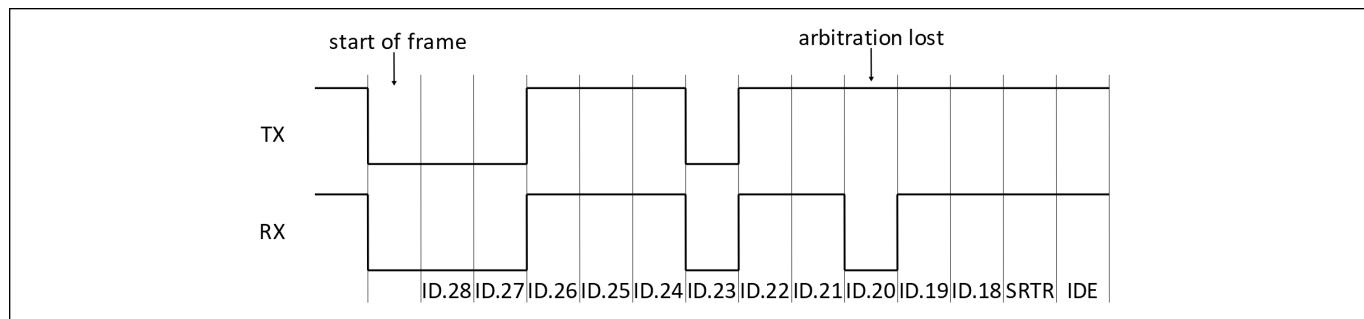

Fig. 27.6: Example of arbitration lost bit number interpretation; result: ALC = 08

Table 27.2: Arbitration loss capture location

BITS					DECIMAL VALUE	FUNCTION
ALC.4	ALC.3	ALC.2	ALC.1	ALC.0		
0	0	0	0	0	00	arbitration lost in bit 1 of identifier
0	0	0	0	1	01	arbitration lost in bit 2 of identifier
0	0	0	1	0	02	arbitration lost in bit 3 of identifier
0	0	0	1	1	03	arbitration lost in bit 4 of identifier
0	0	1	0	0	04	arbitration lost in bit 5 of identifier
0	0	1	0	1	05	arbitration lost in bit 6 of identifier

Table 27.2: Arbitration loss capture location(continued)

BITS					DECIMAL VALUE	FUNCTION
ALC.4	ALC.3	ALC.2	ALC.1	ALC.0		
0	0	1	1	0	06	arbitration lost in bit 7 of identifier
0	0	1	1	1	07	arbitration lost in bit 8 of identifier
0	1	0	0	0	08	arbitration lost in bit 9 of identifier
0	1	0	0	1	09	arbitration lost in bit 10 of identifier
0	1	0	1	0	10	arbitration lost in bit 11 of identifier
0	1	0	1	1	11	arbitration lost in bit SRTR
0	1	1	0	0	12	arbitration lost in bit IDE
0	1	1	0	1	13	arbitration lost in bit 12 of identifier
0	1	1	1	0	14	arbitration lost in bit 13 of identifier
0	1	1	1	1	15	arbitration lost in bit 14 of identifier
1	0	0	0	0	16	arbitration lost in bit 15 of identifier
1	0	0	0	1	17	arbitration lost in bit 16 of identifier
1	0	0	1	0	18	arbitration lost in bit 17 of identifier
1	0	0	1	1	19	arbitration lost in bit 18 of identifier
1	0	1	0	0	20	arbitration lost in bit 19 of identifier
1	0	1	0	1	21	arbitration lost in bit 20 of identifier
1	0	1	1	0	22	arbitration lost in bit 21 of identifier
1	0	1	1	1	23	arbitration lost in bit 22 of identifier
1	1	0	0	0	24	arbitration lost in bit 23 of identifier
1	1	0	0	1	25	arbitration lost in bit 24 of identifier
1	1	0	1	0	26	arbitration lost in bit 25 of identifier
1	1	0	1	1	27	arbitration lost in bit 26 of identifier
0	1	1	0	0	28	arbitration lost in bit 27 of identifier
1	1	1	0	1	29	arbitration lost in bit 28 of identifier
1	1	1	1	0	30	arbitration lost in bit 29 of identifier
1	1	1	1	1	31	arbitration lost in bit RTR

27.4.5.2 Error Capture

The error code capture (ECC) register contains the type and location of bus errors and can only be read by CPU but not written by it. If the bus error interrupt is enabled, a bus error interrupt will be generated once a bus error occurs. The position of the current bit in BSP is captured into the ECC. This register's value is fixed until the user software reads the contents of the ECC. After this value is read, the capture mechanism is activated again. Reading the corresponding bit in the interrupt register will clear this bit, and no bus error interrupt will be generated before the ECC register is read.

The error types represented by the values in the ECC register are shown as follows.

Table 27.3: Type of error catch

BIT ECC.7	BIT ECC.6	FUNCTION
0	0	bit error
0	1	form error
1	0	stuff error
1	1	other type of error

Table 27.4: Error catch location

BIT ECC.4	BIT ECC.3	BIT ECC.2	BIT ECC.1	BIT ECC.0	FUNCTION
0	0	0	1	1	start of frame
0	0	0	1	0	ID.28 to ID.21
0	0	1	1	0	ID.20 to ID.18
0	0	1	0	0	bit SRTR
0	0	1	0	1	bit IDE
0	0	1	1	1	ID.17 to ID.13
0	1	1	1	1	ID.12 to ID.5
0	1	1	1	0	ID.4 to ID.0
0	1	1	0	0	bit RTR
0	1	1	0	1	reserved bit 1
0	1	0	0	1	reserved bit 0
0	1	0	1	1	data length code
0	1	0	1	0	data field
0	1	0	0	0	CRC sequence
1	1	0	0	0	CRC delimiter
1	1	0	0	1	acknowledge slot

Table 27.4: Error catch location(continued)

BIT ECC.4	BIT ECC.3	BIT ECC.2	BIT ECC.1	BIT ECC.0	FUNCTION
1	1	0	1	1	acknowledge delimiter
1	1	0	1	0	end of frame
1	0	0	1	0	intermission
1	0	0	0	1	active error flag
1	0	1	1	0	passive error flag
1	0	0	1	1	tolerate dominant bits
1	0	1	1	1	error delimiter
1	1	1	0	0	overload flag

27.4.5.3 RX Error Counter Register (RXERR)

The RXERR's value represents the current number of received errors, and this register is initialized to logical '0' after hardware reset. In the operating mode, this register can only be read by CPU and write in the reset mode. RXERR is set to logical '0' if a bus shutdown event occurs. At this time, the bus is OFF, and the write operation to this register does not work.

It should be noted that CPU can modify the value of RXERR only in the reset mode. In this case, the error state may change, and the error warning interrupt and error passive interrupt will not occur unless the reset mode is exited.

27.4.5.4 TX Error Counter Register (TXERR)

The TXERR's value represents the current number of send errors. In the operating mode, this register can only be read by CPU and write in the reset mode. This register's value is initialized to logical '0' after hardware reset. If a bus shutdown event occurs, the TXERR's value is set to 127, so that the shortest time (128 bus idle signals) defined by the protocol can be calculated. Reading the TXERR's value during this period can obtain the status information of bus shutdown recovery. If the bus is OFF, a write to TXERR ranging from 0 to 254 will clear the Bus Off flag, and the controller will wait for 11 consecutive recessive bits (Bus Idle) to appear once after clearing the reset mode.

Writing 255 into TXERR by CPU will generate a bus shutdown event. It should be noted that CPU can only change the value of this register by force in the reset mode. In this case, the error or bus state may change, and the error warning interrupt or error passive interrupt will not be affected by the new value unless the reset mode is exited again. After the reset mode is exited, the TXERR's value still operates as if the bus was shut down due to a bus error, which means that the register will enter the reset mode again, the TXERR's value is initialized to 127, the RXRERR's value is initialized to 0, and related statuses and interrupt registers are reset. At this time, exiting the reset mode will execute the bus shutdown recovery process defined by the protocol (waiting for 128 bus idle signals). If the reset

mode is enabled again before the bus is turned off and restored ($\text{TXERR} > 0$), the bus will remain OFF and the TXERR 's value will be frozen.

27.4.5.5 Error Limit Setting

The error warning limit can be set by the **EWLR** register, whose default value is 96 (after hardware reset). This register can be read or written by CPU in the reset mode, while it can only be read in the operating mode. When at least one of the two error count values from **RXERR** and **TXERR** is greater than or equal to the value set in the **EWLR** register, the **ES** bit in the **SR** register will be set, and otherwise it will be cleared. Then, if the **EIE** bit in the **IER** register is set, an error warning interrupt will be generated. It is worth noting that this register can only be operated in the reset mode. The operation of this register may cause the error state to change, and the error warning interrupt will not be generated unless the reset mode is exited again.

27.4.6 Bit Timing

The timing diagram is as follows:

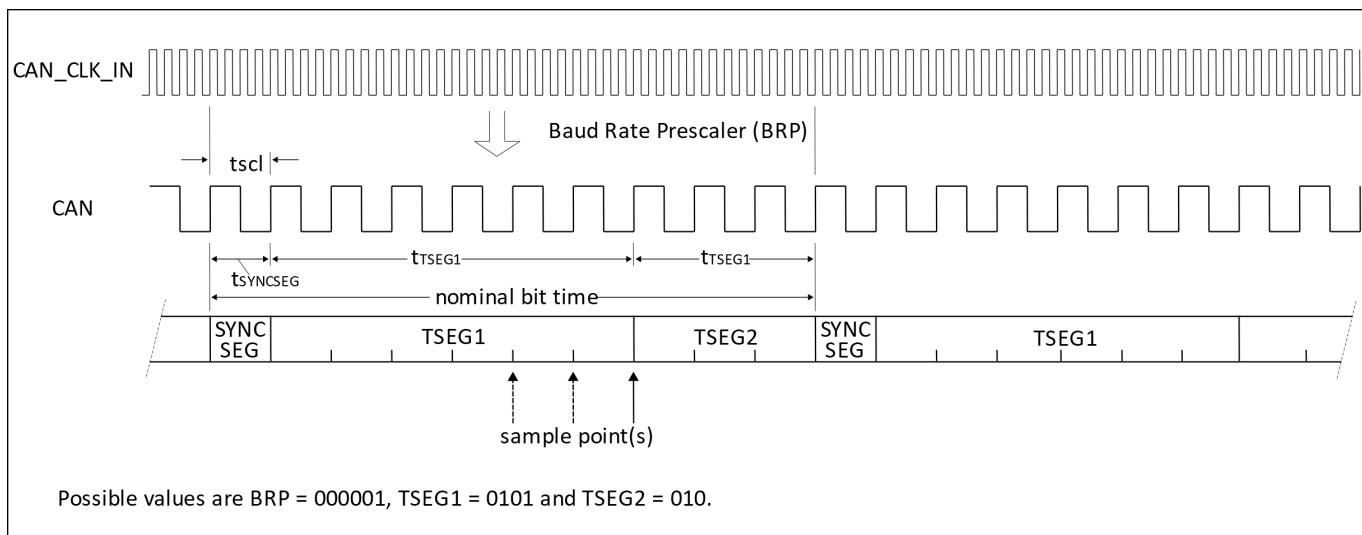

Fig. 27.7: General structure of a bit period

27.4.6.1 Baud Rate Prescaler (BRP)

The cycle of the system clock **tscl** of the ISO11898 controller can be set, and this determines the timing of each bit. The calculation formula of ISO11898 system clock is as follows:

$$\text{tscl} = 2 * \text{tCLK} * (32 * \text{BRP.5} + 16 * \text{BRP.4} + 8 * \text{BRP.3} + 4 * \text{BRP.2} + 2 * \text{BRP.1} + \text{BRP.0} + 1)$$

27.4.6.2 Synchronization Jump Width (SJW)

To compensate the phase shift between the clock oscillators of different bus controllers, any bus controller must resynchronize at the edge of any related signal currently being transmitted. SJW defines the maximum number of clock cycles that a bit cycle can shorten or extend through one resynchronization:

$$t_{SJW} = tscl * (2 * SJW.1 + SJW.0 + 1)$$

27.4.6.3 Sampling (SAM)

When the SAM bit in the BTR1 register is 1, the bus will be sampled three times. This mode suits medium and low speed buses, and this is beneficial to the filter in the bus. If the SAM bit is 0, the bus will only be sampled once. This mode suits the high-speed bus.

27.4.6.4 Time Segment (TSEG)

TSEG, consisting of TSEG1 and TSEG2 in the BTR1 register, determines the number of clocks and sampling point position of each bit, with calculation formula as follows:

$$t_{SYNCSEG} = 1 * tscl$$

$$t_{TSEG1} = tscl * (8 * TSEG1.3 + 4 * TSEG1.2 + 2 * TSEG1.1 + TSEG1.0 + 1)$$

$$t_{TSEG2} = tscl * (4 * TSEG2.2 + 2 * TSEG2.1 + TSEG2.0 + 1)$$

28

MJPEG

28.1 Overview

Motion Joint Photographic Experts Group (MJPEG), a video encoding format, can be accurate to frame editing and multi-layer image processing. The motion video sequence is treated as continuous still images, and this compression format compresses each frame separately and completely. Compressing the original data in the YCbCr format can greatly save the memory space occupied by a frame of image.

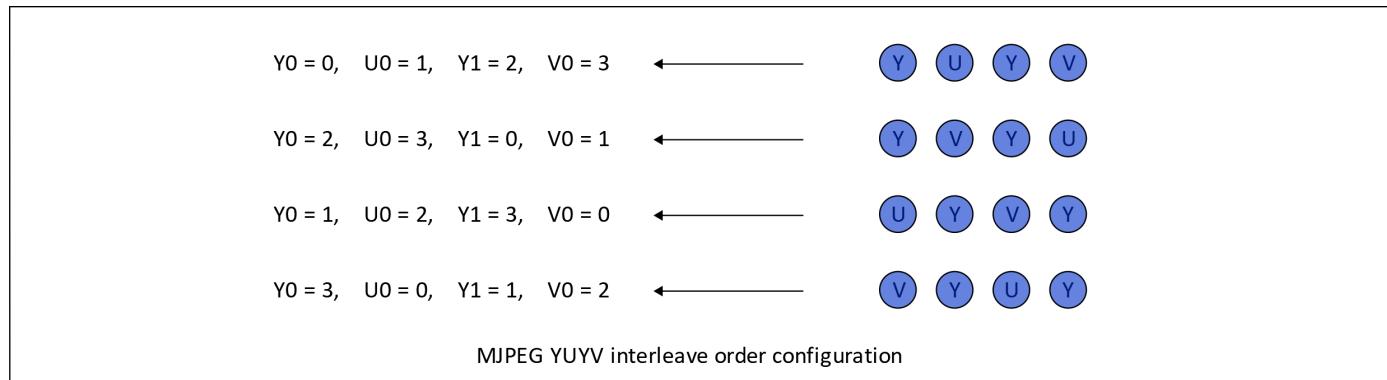

28.2 Features

- Configurable input formats:
 - YCbCr 4:2:2 planar or packed format
 - YCbCr 4:2:0 planar format
 - YCbCr 4:0:0
- Configurable arrangement order of Y, Cb and Cr input data
- Free configuration of quantization coefficient table
- Supports software and linked modes
- Supports swap mode
- Supports kick mode
- Reserves jpg header space and automatically adds jpg tail
- Caches up to 4 images continuously
- Multiple application interrupts are beneficial to flexible use and error prompt

28.3 Functional Description

28.3.1 Input Configuration

You can select the YCbCr format of input data by setting the <REG_YUV_MODE> bit in the register MJPEG_CONTROL_1, including YCbCr 4:2:2 planar or packed format, YCbCr 4:2:0 planar format, and YCbCr 4:0:0 grayscale image. When the YCbCr 4:2:2 packed format is selected, the order of Y, Cb and Cr can be configured by the high 8 bits of the register MJPEG_HEADER_BYTE. When other formats are selected, the order of Cb and Cr can be set by the <REG_ORDER_U_EVEN> bit in the register MJPEG_CONTROL_1. The configuration is shown as follows.

28.3.2 Quantization Coefficient Table

The quantization coefficient table can be freely configured by the user. <reg_q_0_00> to <reg_q_0_3F> represents the quantization table of grayscale Y component, while <reg_q_1_00> to <reg_q_1_3F> represents the quantization table of chrominance information Cb and Cr. In the quantization table, the first column is followed by the second column in descending order from the upper left corner. That is, reg_q_0_00 represents the quantized values of the first column on the first row of Y component, reg_q_0_01 represents that of the first column on the second row of the same, reg_q_0_07 represents that of the first column on the eighth row of the same, reg_q_0_08 represents that of the second column on the first row of the same, and so on.

28.3.3 Software Mode and Linked Mode

Setting the <REG_MJPEG_SW_MODE> bit in the register MJPEG_CONTROL_2 to 1 will enable the software mode. In this mode, MJPEG will read the specified frames of original image data from the memory for compression, but the image data must be prepared in advance.

When the <REG_MJPEG_SW_MODE> bit in the register MJPEG_CONTROL_2 is cleared to 0, the linked mode is enabled. In this mode, MJPEG will process the output of CAM as its input by taking 8*8 data blocks as a unit. After CAM writes 8 lines of data into the memory, MJPEG will start to work. The memory space processed by MJPEG will be released to CAM for reuse, so that CAM can link with MJPEG using the storage space that is less than the size of an image.

28.3.4 Swap Mode

In the swap mode, MJPEG's storage space will be evenly divided into two blocks. When the space of one block is used up, an interrupt will be generated to inform the software to read out the data, and then MJPEG will write data into the other block. Two blocks are used alternatively, so that you can process data with the storage space that is less than the size of a frame of image.

28.3.5 Kick Mode

When the <REG_SW_KICK_MODE> bit in the register MJPEG_CONTROL_2 is set to 1, the kick mode is enabled. In this mode, every time one "1" is written to the <REG_SW_KICK> bit in the register MJPEG_CONTROL_2, one compression will be performed. The number of compressed rows is determined by the <REG_SW_KICK_HBLK> bit in the register MJPEG_YUV_MEM_SW. It should be noted that the kick mode can only be used in the software mode, but not in the linked mode.

28.3.6 Jpg Function

The jpg function will automatically leave some bytes of space at the beginning of each frame of data and fill in zeros. The size of this space is set by the low 12 bits of the register MJPEG_HEADER_BYTE. If automatic padding of jpg tail is enabled, two bytes of data will be added at the end of each frame of data, and the value of the two bytes is 0xFFD9.

28.3.7 Cached Image Information

The module contains four FIFOs to record the image address, image size, and quantization coefficient. Every time this module completely writes a frame into the memory, it will record the start address, image size, and quantization coefficient of this frame of image in FIFO. However, when the memory is insufficient or four FIFOs are full, the module will automatically discard the information of the incoming image. In the part where the image information has been taken out, the oldest image information will be removed by performing the pop operation through APB. Then, FIFO will automatically push data to ensure the timing of the image information in FIFO.

28.3.8 Multiple Interrupts (Separately Configured)

- A. Normal interrupt: You can set to generate an interrupt after a fixed number of images are written
- B. Camera interrupt: When CAM overflows as MJPEG's processing speed cannot keep up with the speed of writing in CAM, an interrupt will be generated
- C. Memory interrupt: When the memory is rewritten, an interrupt will be generated
- D. Frame interrupt: When there are more than 4 unprocessed images, an interrupt will be generated
- E. Swap interrupt: When a memory block is full in the swap mode, an interrupt will be generated

29.1 Overview

JDEC can decode the JPG compressed images in memory into the original images, and then convert them into RGB format for display through the YUV2RGB module.

29.2 Features

- Supports YUV400/YUV420/YUV422 formats.
- Adjustable quantization coefficient: 1–75, 100.
- Supports swap mode
- Supports Skip Mode, where the JPG header is automatically skipped.
- Buffer with up to 16 JPG images.
- Supports flexible interrupt configuration mode, which can set an interrupt at the specified number of images or all complete interrupt.

29.3 Functional Description

29.3.1 Output Configuration

You can select the YCbCr format of output data by setting the <REG_YUV_MODE> bit in the register JDEC_CONTROL_1, including YCbCr4:2:2 planar format, YCbCr4:2:0 planar format, and YCbCr4:0:0 grayscale image. The start address of the output image data is determined by the registers JDEC_YY_FRAME_ADDR and JDEC_UV_FRAME_ADDR. The resolution of the output image data is determined by the register JDEC_FRAME_SIZE, in which the <REG_FRAME_HBLK> bit represents the number of 8×8 blocks in the vertical direction and the <REG_FRAME_WBLK> bit represents the number of 8×8 blocks in the horizontal direction.

29.3.2 Quantization Coefficient

The quantization coefficient can be set by the <REG_Q_MODE> bit in the register JDEC_CONTROL_1. When the set value does not exceed 75, the quantization coefficient is the set value. When that exceeds 75, the quantization coefficient is 100.

29.3.3 Swap Mode

In Swap Mode, a space with a size of two frames of output images is used as a buffer. When one frame of space is full, the decompressed image data continues to be stored in another frame of space buffer. The two frames of space are used alternately back and forth. This mode can be linked with the Display Module to improve efficiency.

29.3.4 Skip Mode

When the <REG_HDER_SKIP> bit in the register JDEC_HEADER_SKIP is set to 1, the Skip Mode is enabled. Then, the JDEC Module takes the value that equals to the start address of JPG image set by the <REG_JP_ADDR> bit in the register JDEC_FRAM_PUSH plus the number of byte offset set by the <REG_HDER_SKIP_BYT> bit in the register JDEC_HEADER_SKIP as the final actual start address for decompressing JPG images. This applies to the scenario of skipping JPG header information.

29.3.5 Buffer

The JDEC input buffer can store the information of up to 16 JPG images. Every time one “1” is written to the <REG_JP_PUSH> bit in the register JDEC_FRAM_PUSH, the free space of the buffer decreases. Every time JDEC decompresses a JPG image, this free space increases. The number of JPG images to be decompressed in the current buffer can be obtained by reading the <JP_FRAME_CNT> bit in the register JDEC_FRAM_STS. The <FRAME_VALID_CNT> bit in the register JDEC_CONTROL_3 indicates the number of decompressed images yet not processed.

29.3.6 Operating Process

- Disable the JDEC Module and clear the REG_MJ_DEC_ENABLE bit in the register JDEC_CONTROL_1.
- Set the formats of output image data as YUV422/YUV420/YUV400/…
- Choose whether to enable Swap Mode according to the application scenario.
- Set the quantization coefficient of images.
- Set the start addresses of Y and UV components of the output image in memory respectively.
- Set the numbers of horizontal and vertical 8×8 blocks according to the resolution of image data.
- If you need to enable Skip Mode, set the number of bytes to skip.
- Enable the JDEC Module and set the REG_MJ_DEC_ENABLE bit in the register JDEC_CONTROL_1 to “1” .
- Write the start address of the input JPG images and the command to cache in the buffer synchronously, that is,

writing the start address of JPG images into the register JDEC_FRAM_PUSH and setting its <REG_JP_PUSH> bit to “1” .

29.4 Precautions

- The start address of JPG image in memory shall be 8-byte aligned.
- The resolution of JPG images must be an integer multiple of 8.
- Currently, only the standard Huffman coding is supported.

30.1 Overview

VENC follows the H264 video coding standard, which mainly compresses objects by prediction and motion compensation, and improves image quality by a loop filter, while meeting the requirements of stream transmission and image quality.

30.2 Features

- 1920x1080p@30fps + 640x480@30fps, BP/MP
- Input: Semi-Planar YCbCr 4:2:0
- Output: NALU(Network Abstract Layer Uint) in byte stream format
- CBR/VBR mode
- Up to 8 ROI
- Up to 16 OSD coding areas
- Supports software and linked modes
- Dynamically configurable max/min quantization parameters
- Dynamically configurable I/P-frame target bit
- Dynamically configurable I-frame distance

30.3 Functional Description

30.3.1 Software Mode and Linked Mode

Software Mode: The hardware interacts with the software in the unit of frame. The software sets that the hardware compresses one frame only after one frame is started, and a frame interrupt is returned after compression is completed. The input frame memory shall contain at least one frame.

Linked Mode: The software sets the <CFG_S_ENC_SEQ_EN> or <CFG_ENC_SEQ_EN> bit in H264_ENCODER_CTRL to enable sequence encoding. The hardware automatically detects the state of the input frame and compresses it. Until software pulls down Sequence Enable, the hardware stops compression (ending at a complete frame) and the sequence interrupt is returned. When each frame in the sequence is finished, a frame interrupt is returned.

30.3.2 CBR/VBR Mode

If <NUM_IMB_BITS> or <S_NUM_IMB_BITS> in CORE_REG23 is set to 0, the stream is in VBR Mode. If it is not 0, it is in CBR Mode. In VBR Mode, I/P-frame fixed quantization parameters (CORE_REG3/CORE_REG5) shall be set. It is not recommended to switch modes when hardware is working.

30.3.3 Dual-Stream

The frame enable, frame interrupt, sequence enable, and sequence interrupt of the two streams are configured separately. Essentially, the frame rate of two streams shall be the same, but the resolution and other compression parameters can be different.

30.3.4 Region of Interest (ROI)

A single stream supports up to 8 ROI areas, and each area has its own enabling and start/end macroblock position settings. It is necessary to set the <CFG_ROI_UPD> bit in H264_ROI_MODE or the <CFG_S_ROI_UPD> bit in H264_S_ROI_MODE to “1”, to make the new settings take effect. The hardware synchronizes ROI settings for each frame.

30.3.5 OSD Coding Area

The hardware supports up to 16 OSD areas, and H264 OSD EN decides the OSD area of each stream as configured in the software. The OSD area is represented by the start/end macroblock position.

30.3.6 Dynamically Configurable Max/Min Quantization Parameters

To provide a better control stream, after the software sets CORE_REG31, it is necessary to set H264_ENCODER_CTRL (the <CFG_QR_UPD> and <CFG_S_QR_UPD> bits set two streams respectively) to make the new setting value take effect. The hardware will synchronize the new setting value in the unit of GOP to adjust the quantization parameters dynamically.

30.3.7 Dynamically Configurable I/P-Frame Target Bit

The software can set CORE_REG23/CORE_REG24 to adjust the target bit of I/P-frame. After CORE_REG23/CORE_REG24 is set, it is necessary to set H264_ENCODER_CTRL (the <CFG_QR_UPD> and <CFG_S_QR_UPD> bits set two streams respectively) to make the new setting value take effect. The hardware will synchronize the new setting value in the unit of GOP (CBR Mode).

30.3.8 Dynamically Configurable I-Frame Distance

After the software sets CORE_REG8, it is necessary to set H264_ENCODER_CTRL (the <CFG_QR_UPD> and <CFG_S_QR_UPD> bits set two streams respectively) to make the new setting value take effect. The hardware will synchronize the new setting value in the unit of GOP (CBR/VBR available).

30.3.9 Video Sequence Interrupt

In Linked Mode, when software pulls down Sequence Enable, the hardware generates sequence interrupt after processing the current frame (<S_SEQ_DONE_INT> or <SEQ_DONE_INT> bit in VDO_INT), and this interrupt requires the software to set the interrupt clear (<S_SEQ_DONE_INT_CLR> or <SEQ_DONE_INT_CLR> bit in VDO_INT_CLR). This interrupt can be ignored by masking (<S_SEQ_DONE_INT_MASK> or <SEQ_DONE_INT_MASK> bit in VDO_INT_MASK).

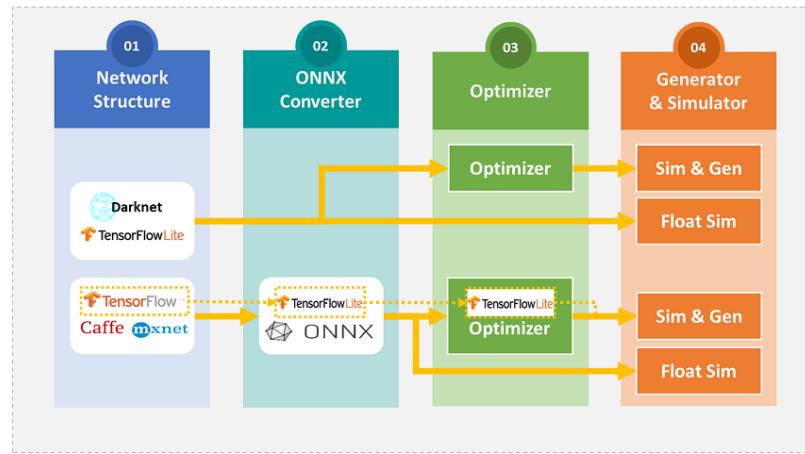

30.3.10 Frame Interrupt

In Software Mode and Linked Mode, the frame interrupt (<S_FRM_DONE_INT> or <FRM_DONE_INT> in VDO_INT) will be generated as soon as the hardware compresses one frame. This interrupt requires the software to set the interrupt clear (<S_FRM_DONE_INT_CLR> or <FRM_DONE_INT_CLR> bit in VDO_INT_CLR). This interrupt can be ignored by masking (<S_FRM_DONE_INT_MASK> or <FRM_DONE_INT_MASK> bit in VDO_INT_MASK).

30.3.11 Input Cache Overflow Alert

If the video compression speed is much lower than the camera pixel, buffer overflow will occur at output. The software can detect that through the status register VDO_SRC_R_DBG (<SRC_WR_OV_RD> bit) or VDO_S_SRC_R_DBG (<S_SRC_WR_OV_RD> bit).

31.1 GUI Flow chart

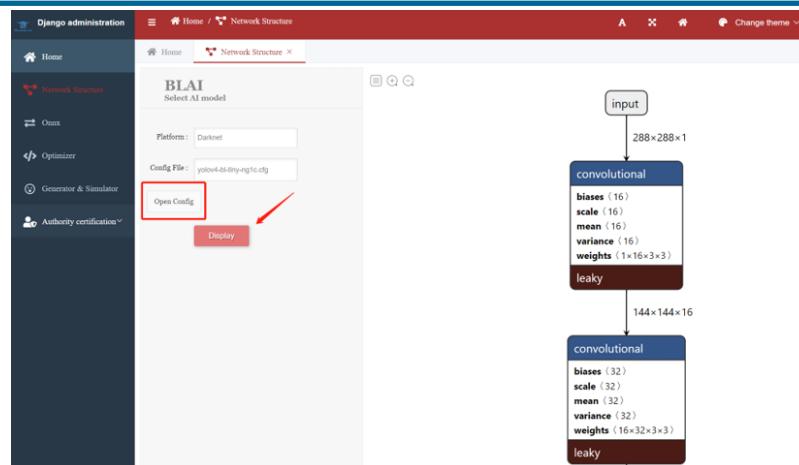

31.2 Network Structure

To display model structure via Netron on GUI, you have to choose a platform and a config file that you want to display.

Platform:

Darknet, Tensorflow, Caffe, Mxnet, ONNX

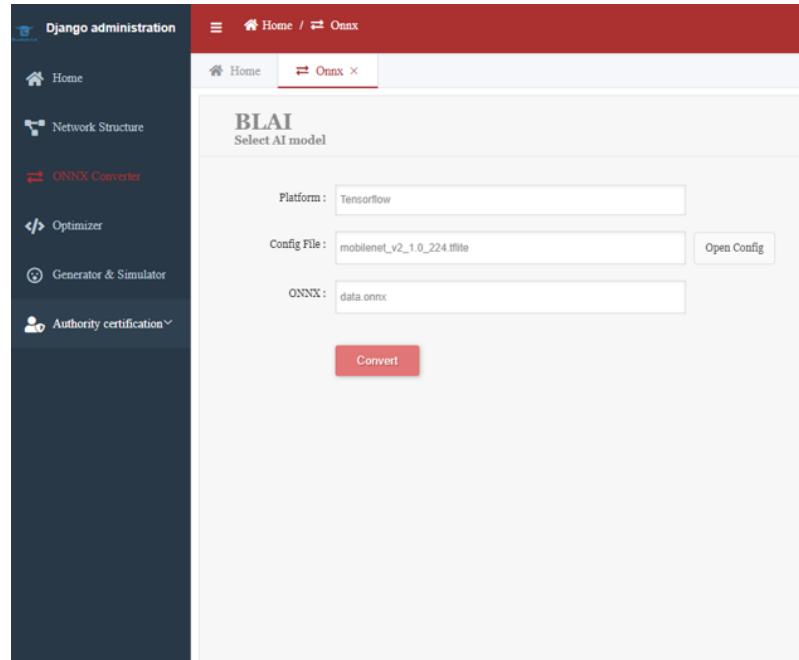

31.3 ONNX Converter

To convert your platform into ONNX, you have to choose a platform and name the ONNX file.

Platform:

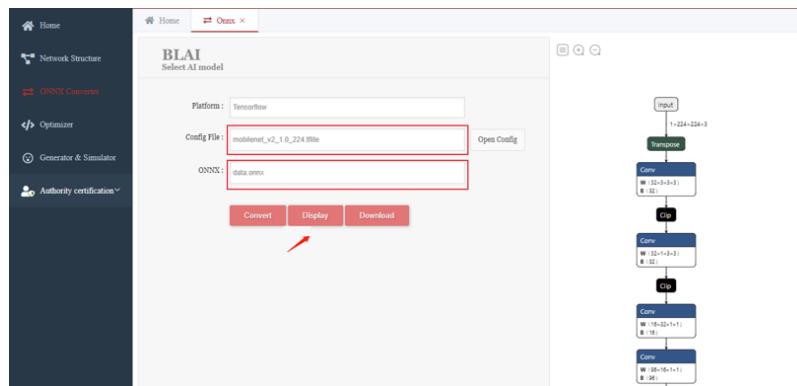

Tensorflow, Caffe, Mxnet

(DarkNet, Tensorflow Lite is supported directly.)

The screenshot shows the BLAI interface for the ONNX Converter. The sidebar includes Home, Network Structure, ONNX Converter, Optimizer, Generator & Simulator, and Authority certification. The main area has tabs for Home and ONNX. Under ONNX, it says "BLAI Select AI model". It shows a "Platform: Tensorflow", a "Config File: mobilenet_v2_1.0_224.tflite", and an "ONNX: data.onnx". A red box highlights the "Convert" button.

After you press “convert” on ONNX Converter, the screen will show two more buttons which you can choose to “display” it on GUI or “download” it.

31.4 Optimizer

The optimizer section allows you to quantize float to fixed points.

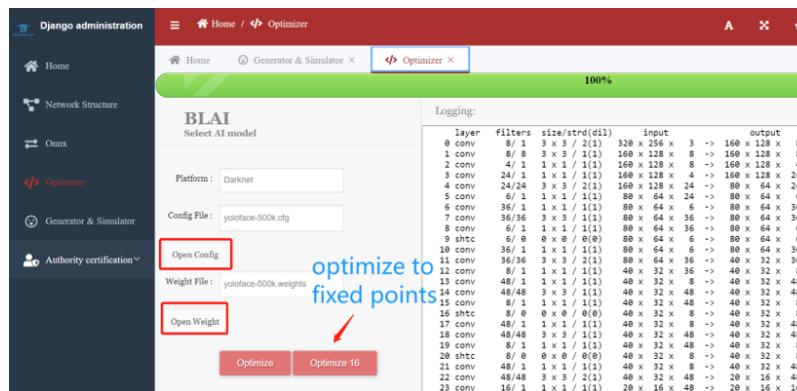

“Optimize” : spend more time, high accuracy

“Fast Optimize” : spend less time, more accuracy loss

Platform:

Darknet, Tensorflow, ONNX

(BLAI NPU also support optimizer format on Tensorflow Lite)

31.5 Generator & Simulator

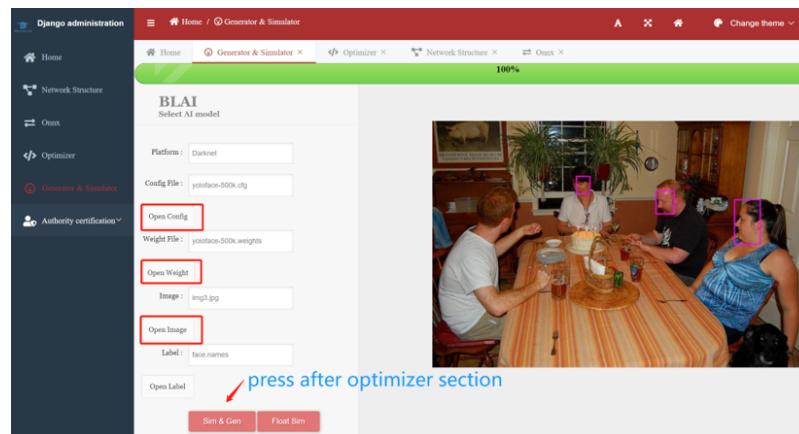

“**Sim&Gen**” will predict the image with 8 bits quantized weights after you have done the Optimizer section, and generate BLAI NPU instruction

“**Float Sim**” will predict the image with 32 bits unquantized weights.

Platform:

Darknet, Tensorflow, ONNX

(BLAI NPU also support optimizer format on Tensorflow Lite)

32.1 Overview

The Neural Processing Unit (NPU), also called AI accelerator, is an electronic circuit dedicated to deep learning algorithms. It can implement all the control and arithmetic logic necessary to execute machine learning algorithms, usually with a separate data memory and special instruction set architecture. NPU aims to provide higher efficiency and performance for deep learning algorithms than the general central processing unit (CPU). NPU uses a large number of computing modules to utilize high data-level parallelism, a relatively large buffer/memory to apply the data reuse patterns, and a finite data width operator for deep learning fault tolerance.

32.2 Features

- AI computing power: strong:0.1 TOPS
- Supports 8-bit operation
- Compatible with TensorFlowlite/ONNX/Caffe/Mxnet/Darknet/Pytorch model, and multiple frameworks
- Provide PC-side easy-to-use development tools, including model conversion, model quantification, performance prediction, and accuracy verification
- Supports single-layer instruction mode and multi-layer instruction mode
- Supports the maximum feature graph $4096 \times 4096 \times 4096$ (width \times height \times depth)

32.3 Feature List

Type	Operators	Applicable Subset Spec.	Processor
Convolution	Conv	1x1 up to 7x7	NPU
	Depthwise Conv	1x1 up to 7x7	NPU
	Pad	same	NPU
	Deconvolution	use Upsample + Conv	NPU

Type	Operators	Applicable Subset Spec.	Processor
Pooling	MaxPool(2x2)	Stride 2	NPU
	MaxPool(3x3)	3x3	NPU
	AveragePool	Stride 1, 2	DSP
	GlobalAveragePool		DSP
	GlobalMaxPool		DSP
Activation	Relu		NPU
	LeakyRelu		NPU
	Relu-n	$n > 0$ (Relu6)	NPU
	Mish	Look up table	NPU
	ELU	Look up table	NPU
	PReLU		DSP
	Sigmoid		DSP
Other processing	BatchNormalization		DSP
	Add (shortcut)		NPU
	Concat (route)		NPU
	Fully Connected		NPU
	Mul		NPU
	Slice		DSP

33.1 Overview

The Interprocessor Communication (IPC) is a communication mechanism between multi-core processors. BL808 has three heterogeneous cores, and any two cores can communicate with each other through IPC.

33.2 Features

- Each core has an independent 32-bit IPC channel
- Any two cores can communicate with each other

33.3 Functional Description

33.3.1 Basic Principle

Each core has six IPC registers: IPCx_TRI, IPCx_STS, IPCx_ACK, IPCx_IEN, IPCx_IDIS and IPCx_ISTS. The length of each register is 32-bit, and each bit corresponds to one channel of IPC. The cores M0, LP and D0 correspond to IPC0, IPC1 and IPC2 respectively. When one core needs to issue a notification to another, it only needs to write “1” to the corresponding channel of IPCx_TRI of the receiving core. At this time, the corresponding channel of IPCx_STS of the receiving core is set to “1”. If the interrupt of the corresponding IPC channel of the receiving core is also enabled, an interrupt will be received, indicating that the receiving core receives the notification from the other core.

33.3.2 Operating Process

For example, the core x sends a notification to the core Y, and the channel z is used. The operation flow is as follows:

- The core y enables the interrupt of channel z. That is, the core y performs operation $\text{IPCy_IEN} = 1 \ll z$
- The core x writes 1 to the bit z in the register IPCy_TRI. That is, core x performs operation $\text{IPCy_TRI} = 1 \ll z$
- Upon receiving the interrupt, the core y responds to the core x. That is, the core y performs operation $\text{IPCy_ACK} = 1 \ll z$

- The core y performs the notified application layer related operation

The operation flow is as follows:

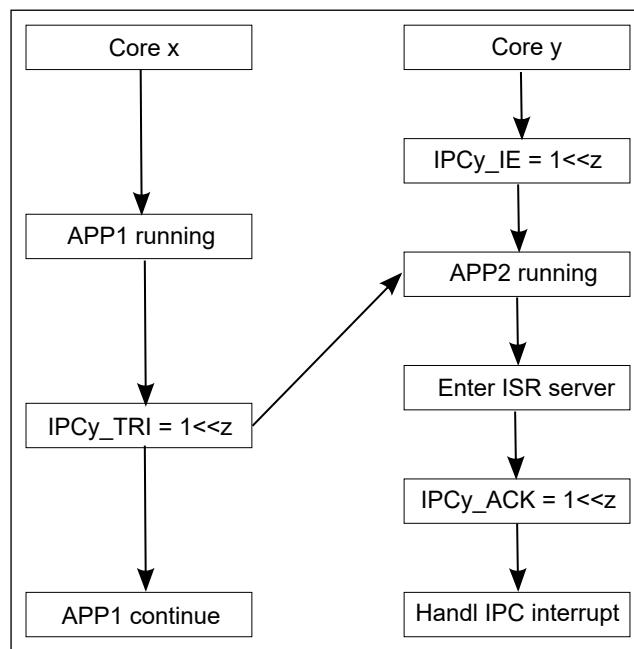

Fig. 33.1: IPC Flow

34.1 Overview

Low power consumption is an important indicator of IoT applications. The chip's CPU supports the working mode, idle power saving mode, and sleep mode. You can select a proper mode according to the current application scenario to reduce the chip's power consumption and prolong the battery life.

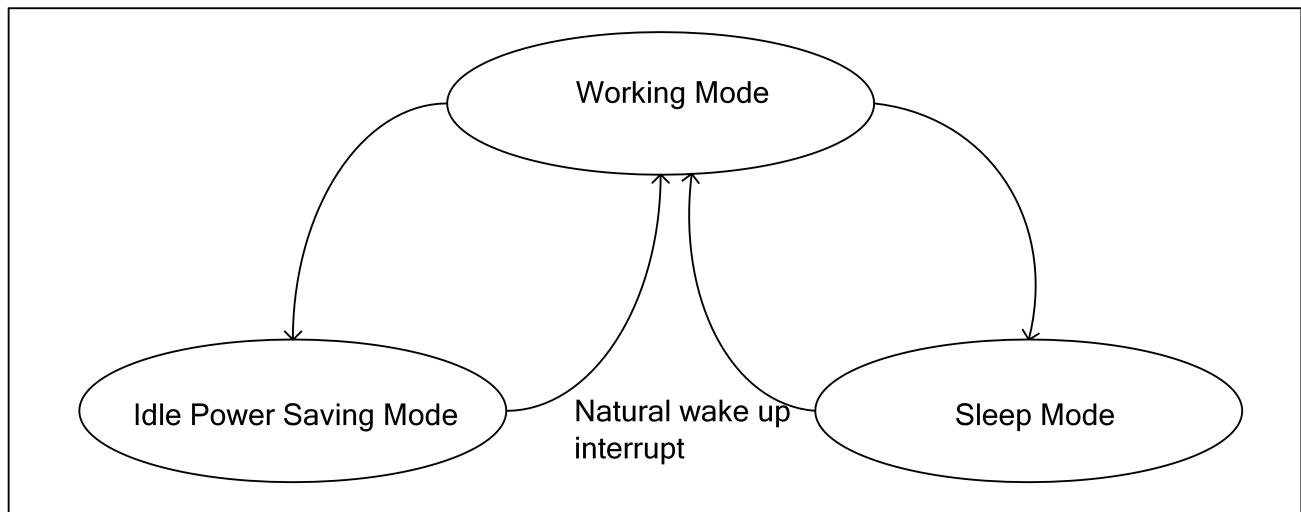

Fig. 34.1: Low power modes

34.2 Features

- Clock control: clock control of peripherals in GLB, small-scale power saving, and fast response speed
- Sleep control (PDS): 4 levels (PDS 1/2/3/7), large-scale power saving, moderate response speed
- Deep sleep control (HBN): 4 levels (HBN 0/1/2/3), global power saving, and long response time

34.3 Functional Description

34.3.1 Power Domain

There are 7 power domains in the BL808 chip, with main functions as follows:

- PD_AON_RTC
 - RC32K/XTAL32K control register is reserved
 - RTC Counter clock source selection function
 - RTC can be used for wake-up or LED flashing
- PD_AON
 - HBN state machine controls power supply/isolation/reset/clock
 - Maintain internal voltage output selection
 - AON_PIN (GPIO9/10/11/12/13/40/41) pin wake-up control
 - HBN_OUT0_PIR (Acomp0/Acomp1/bor/pir) wake-up mask, enable register, and interrupt status register
 - BOR (Brown Out Reset) function
- PD_AON_HBNCore
 - Partial power control register
 - 4 KB HBN_RAM, which is used to save program data before the PDS/HBN mode is enabled, so that data will not disappear in these modes
 - PIR digital control: PIR is a Passive Infra-Red (PIR) sensor, a peripheral in HBN area, which can be used as HBN wake-up source
 - AON_PIN control and IO retention function in HBN/PDS mode
 - Acomp0 and Acomp1 configuration, GPADC clock source selection and configuration
- PD_CORE
 - HBN state machine controls power supply/isolation/reset/clock
 - Reserved 64 KB RAM
 - WIFI/BLE timer control
 - 160KB WRAM/EM
- PD_CORE_MISC_DIG
 - M0 CPU and its peripherals

- Chip's global register
- PD_USB
 - USB digital controller
- PD_MM
 - D0 CPU and its peripherals, PSRAM
 - Codec
 - VRAM 32~96KB
 - BLAI

Each power domain is controlled by 9 different power modes as shown below:

Table 34.1: Power mode

NO.	Scenario	Power Domain						
		PD_AON_-RTC	PD_AON	PD_AON_HBN-CORE	PD_-CORE	PD_CORE_MISC_-DIG	PD_USB	PD_MM
1	Normal	ON	ON	ON	ON	ON	ON	ON
2	PDS1	ON	ON	ON	ON	ON	ON	OFF
3	PDS2	ON	ON	ON	ON	ON	OFF	ON
4	PDS3	ON	ON	ON	ON	ON	OFF	OFF
5	PDS7	ON	ON	ON	ON	OFF	OFF	OFF
6	HBN0	ON	ON	ON	OFF	OFF	OFF	OFF
7	HBN1	ON	ON	OFF	OFF	OFF	OFF	OFF
8	HBN2	ON	OFF	OFF	OFF	OFF	OFF	OFF
9	HBN3	OFF	OFF	OFF	OFF	OFF	OFF	OFF

Note:

- To enter the HBN2 mode, the chip needs to enter the HBN1 mode first, and then turn VDDIO2 off
- In the HBN2 mode, only RTC_Timer is kept, but no wake-up is provided. To quit the HBN2 mode, you only need to resupply power to VDDIO2.
- VDD33_RTC/VDDIO2(AON) share pin encapsulation (QFN88 Type2, QFN68), without HBN2 mode
- The pu_chip must be powered off before entering the HBN3 mode. In this mode, most devices will be powered off, but you can set whether to power RTC off through rtc_pu_chip_sel.

If `rtc_pu_chip_sel` is 1, the RTC power supply is always maintained. If that is 0, it is controlled by `pu_chip`. The value of `rtc_pu_chip_sel` is determined at encapsulation.

34.3.2 Wake-up Source

The chip supports multiple wake-up sources, which can wake up the chip from different power modes.

PDS 1/2/3 can be wake up in the following ways:

- HBN wake-up source
- All GPIO wake-up
- Infrared receiver
- BLE wake-up event
- WIFI wake-up event
- PDS timer

The wake-up sources of other power modes are shown as follows:

Table 34.2: Wakeup source

Power Mode	Wake-up Source
PDS7	PDS timer/PSD_PIN/RTC/AON_PIN/BOR/Pir/Acomp0/Acomp1
HBN0	RTC/AON_PIN/BOR/Pir/Acomp0/Acomp1
HBN1	RTC/AON_PIN
HBN2	Resupply power to VDDIO2
HBN3	Resupply power to pu_chip

34.3.3 Power Modes

Operating mode

The chip provides independent clock control between CPU and peripherals. The GLB and clock sections detail the clock control of each module. The software can perform clock control over CPUs or peripherals that are not in use according to the current application scenario. The clock control provides real-time response, so there is no need to worry about the response time in this working mode.

Power-down sleep mode

The power-down mode consumes less power than the working mode. In the PDS mode, the clocks other than RTC will be controlled and switched to the internal low-speed clocks, and the external crystal oscillator and PLL will be turned off to save more power, so there will be a time delay when entering and exiting this low-power mode. After the

power-down sleep mode is enabled, the data in the OCRAM area can automatically switch to the “retention” state and remain, and automatically exit this state after wake-up.

1. Enter Idle Power Saving Mode

The software can make this module enter the power-down mode through PDS configuration, waiting for processing. After entering the wait for interrupt (WFI) mode, PDS will trigger the clock control module to perform the gate clock operation, and notify the analog circuit to turn off the PLL and external crystal oscillator

2. Exit Idle Power Saving Mode

There are two ways to exit the idle power saving mode. One is that a specific interrupt or event stops the idle state. The other is that the time in PDS_TIM set by the software is met. Both will trigger PDS to exit the power-down mode. Considering that it takes about 1 ms to turn on the crystal oscillator, PDS allows software to turn on the crystal oscillator in advance, to wake up PDS faster. When PDS is ready to wake up, it will notify CPU to exit the WFI mode through interrupt.

HBN

In the sleep mode, most of the chip logic is powered off (Vcore) while the AON power is kept ON, and the internal circuit will not wake up until an external event is received. This mode can achieve ultimate power saving, but it takes the longest response time compared with the first two modes, so it suits the case where the chip does not need to work for a long time, to prolong the battery life. As most circuits will be powered off in this mode, the corresponding register values and memory data will disappear. Therefore, there is a 4 KB HBN_RAM reserved in HBN that will not be powered off in the HBN0 mode. The data or state that the software needs to save can be copied to this memory before the chip enters the sleep mode. When recovering from the sleep mode, the chip can access data directly from RAM, which can usually be used as a record of state or a quick data recovery.

34.3.4 IO Retention

IO retention includes AON_IO retention and PDS_IO retention. In the PDS 0/1/2/3 mode, for the chip’s MISC domain is still powered, GPIO can be controlled by the glb register. After the glb register is powered off, AON_CTRL and PDS can control the IE/PD/PU of AON_IO and PDS_IO.

AON_IO

AON_IO refers to GPIO9/10/11/12/13/14/15/40/41. GPIO40/41 is used as the input and output of XTAL32K by default (it can only be used as AON_IO if it is changed to other pinmux purposes). When the IE/OE of GPIO40/41 is all set to 0, GPIO40/41 multiplexes the analog function XTAL32K_INXTAL32K_OUT. Contrarily, when that is not all set to 0, GPIO40/41 is used as a normal IO function. For example, when GPIO40 is used as a general IO function, reg_en_aon_ctrl_gpio[7] and reg_aon_pad_oe[7] are set to 0, and reg_aon_pad_ie_smt[7] is set to 1.

1. Hardware’s IO retention: HBN can control the IE/PD/PU/OE/O of AON_IO, thus achieving IO retention. When reg_en_aon_ctrl_gpio is 1, reg_aon_gpio_pu controls the pull-up enable of AON_IO and reg_aon_gpio_pd controls the pull-down enable. The reg_aon_gpio_oe controls OE, and aon_led_out[0], [1], and [2] control AON PAD O, respectively. Whereas, IE/SMT can be controlled by reg_aon_gpio_ie_smt no matter the value of reg_en_-

aon_ctrl_gpio is 0 or 1. For example, when reg_en_aon_ctrl_gpio is 0, even if reg_aon_pad_pu is 1, it cannot enable pull-up. But setting reg_aon_gpio_ie_smt to 1 can enable the IE function.

2. Software IO retention: After reg_aon_gpio_iso_mode is set to 1, AON PAD can retain OEO, but PUPD cannot be retained when entering the HBN mode. After HBN wake-up, the AON PAD state will still be retained, and you need to clear reg_aon_gpio_iso_mode before exiting IO retention state. For example, GPIO40 keeps high level in the HBN mode, so you need to configure it as a normal IO function first, then configure it to output high level through the glb register, and finally set reg_aon_gpio_iso_mode to 1 before entering the HBN mode.

PDS_IO

PDS_IO refers to other 32 GPIOs except AON_IO, and they are divided into 3 groups by the physical location of PAD:

- Left: GPIO0–8
- Right: GPIO16–23
- Top: GPIO24–39

1. Hardware IO retention: The IE/PD/PU of PDS_IO can be controlled by the register pds_gpio_i_set, and the same group of GPIOs must hold the same level. For example, if GPIO0 is configured to pull-up, GPIO8 is also configured to pull-up.
2. Software IO retention: When cr_pds_gpio_iso_mode is 1, if cr_pds_gpio_kee_en[0], [1], and [2] is 1 in the PDS7 mode, GPIO0–8, GPIO16–23, and GPIO24–38 enter the GPIO retention state respectively. After PDS7 is woke up, the PDS_IO state will still be retained, so you need to clear cr_pds_gpio_iso_mode to 0 before existing IO retention. The advantage of this IO retention is that the same group of GPIOs can hold different levels.

35.1 Overview

35.1.1 AES

Advanced Encryption Standard (AES) is the most common type of symmetric encryption algorithm. Also known as Rijndael encryption algorithm in cryptography, it is a block encryption standard adopted by the U.S. federal government.

35.1.2 MD5

Message Digest Algorithm 5 (MD5), a widely used cryptographic hash function, can generate a 128-bit (16-byte) hash value, to ensure the integrity and consistency of information transmission.

35.1.3 SHA

SHA256 is a variant of Secure Hash Algorithm 2 (SHA2). SHA2, the successor of SHA1, is a cryptographic hash function algorithm standard designed by the United States National Security Agency. SHA2 has six different variants: SHA224, SHA256, SHA384, SHA512, SHA512/224, and SHA512/256. SHA-512/224 means that the result takes the first 224 bits of SHA-512, and SHA-512/256 means that the result takes the first 256 bits of SHA-512.

35.1.4 CRC

Cyclic Redundancy Check (CRC) is a channel coding technique that generates short fixed-digit check codes based on data including network packets or computer files. It is mainly used to detect or check possible errors after data transfer or storage. It detects errors based on the principle of division and remainder.

35.1.5 GMAC

GMAC is to use Galois Field (GF, finite field) multiplication to calculate the MAC value of a message.

35.2 Features

- Encryption and decryption of aes128, aes192, and aes256
- Crc16, crc32, md5, sha256, and sha512
- Trng
- Gmac

35.3 Principle

AES means that the same key is used for encryption and decryption, with encryption process as follows:

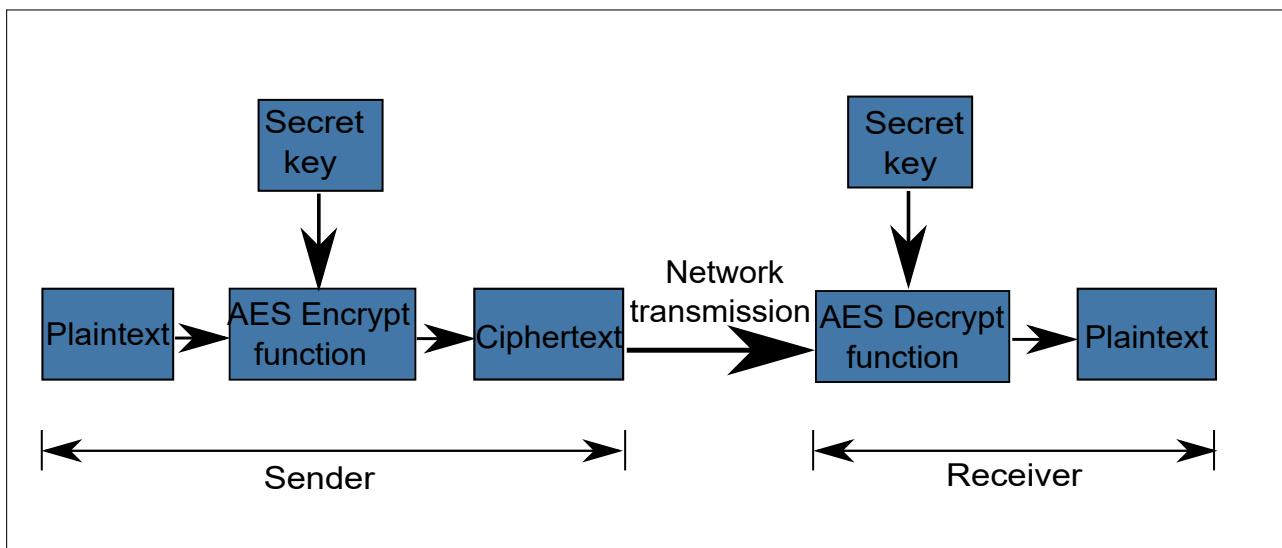

Fig. 35.1: AES Encryption Process

The following briefs the functions and significance of each part:

- Plaintext (P): unencrypted data.
- Key (K): The key used to encrypt plaintext. In symmetric encryption algorithm, encryption and decryption share one key. The key is generated by negotiation between the receiver and the sender, but it cannot be directly transmitted over network. Otherwise it will leak the key. Usually, the key is encrypted by an asymmetric encryption algorithm, and then transmitted to the other side over network, or the key is discussed face to face. The key must not be leaked. Otherwise the attacker will restore the ciphertext and steal confidential data.
- AES encryption function: Let this function be E, then $C = E(K, P)$, where P, K and C denote plaintext, key, and ciphertext, respectively. That is, if plaintext (P) and key (K) are input as the parameters of function, this function

will output ciphertext (C).

- Ciphertext (C): data processed by encryption function.
- AES decryption function: Let this function be D, then $P = D(K, C)$, where C, K, and P denote ciphertext, key, and plaintext, respectively. That is, if ciphertext (C) and key (K) are input as the parameters of function, this function will output plaintext (P).

35.3.1 Implementation of MD5

MD5 can be regarded as a block-based algorithm, as it requires that the length of data processed each time is 512 bits. However, the length of plaintext to be actually processed is not always an integer multiple of 512, so data padding is required. Assuming that the length of the original plaintext message is K, the padding of MD5 is further divided into 2 steps:

1. Append padding bits: 100... are padded after the K bits of the original plaintext message until $512-64 = 448$ bits. The padding rule is that only the first bit is 1, followed by all zeros.
2. Append length: The length of the original message is filled after the result of the first step, and the available storage length is 64 bits. The whole padding process is as follows:

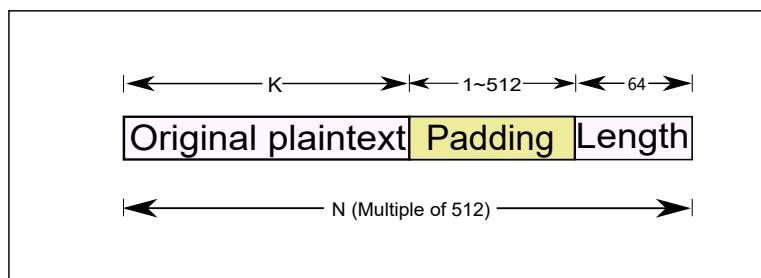

Fig. 35.2: MD5 Padding

Data to be used:

- Four constants: A = 0x67452301, B = 0x0EFCDAB89, C = 0x98BADCFC, D = 0x10325476;
- Four functions: F(X,Y,Z)=(X & Y) | ((~X) & Z); G(X,Y,Z)=(X & Z) | (Y & (~Z)); H(X,Y,Z)=X ^ Y ^ Z; I(X,Y,Z)=Y ^ (X | (~Z));

The message is divided into 512-bit groups for processing. Each group undergoes 4 rounds of transformation. The above 4 constants are used as the initial variables for calculation, to re-output 4 variables, based on which the next group is calculated. For the last group, the 4 variables are the final result, namely MD5 value.

35.3.2 Implementation of SHA256

It is implemented in a way similar to that of MD5. Its rule of data padding is the same as that of MD5. SHA256 uses 8 initial hash values and 64 hash constants.

The 8 initial hash values are as follows:

- $h_0 = 0x6a09e667$
- $h_1 = 0xbb67ae85$
- $h_2 = 0x3c6ef372$
- $h_3 = 0xa54ff53a$
- $h_4 = 0x510e527f$
- $h_5 = 0x9b05688c$
- $h_6 = 0x1f83d9ab$
- $h_7 = 0x5be0cd19$

These initial values are obtained by taking the first 32 bits from the decimal part of the square root of the first 8 prime numbers (2, 3, 5, 7, 11, 13, 17, and 19) in natural numbers.

The 64 constants are as follows:

- 428a2f98 71374491 b5c0fbef e9b5dba5
- 3956c25b 59f111f1 923f82a4 ab1c5ed5
- d807aa98 12835b01 243185be 550c7dc3
- 72be5d74 80deb1fe 9bdc06a7 c19bf174
- e49b69c1 efbe4786 0fc19dc6 240ca1cc
- 2de92c6f 4a7484aa 5cb0a9dc 76f988da
- 983e5152 a831c66d b00327c8 bf597fc7
- c6e00bf3 d5a79147 06ca6351 14292967
- 27b70a85 2e1b2138 4d2c6dfc 53380d13
- 650a7354 766a0abb 81c2c92e 92722c85
- a2bfe8a1 a81a664b c24b8b70 c76c51a3
- d192e819 d6990624 f40e3585 106aa070
- 19a4c116 1e376c08 2748774c 34b0bcb5

- 391c0cb3 4ed8aa4a 5b9cca4f 682e6ff3
- 748f82ee 78a5636f 84c87814 8cc70208
- 90beffa a4506ceb bef9a3f7 c67178f2

Similarly, these constants are obtained by taking the first 32 bits from the decimal part of the cube root of the first 64 prime numbers (2, 3, 5, 7, 11, 13, 17, 19, 23, 29, 31, 37, 41, 43, 47, 53, 59, 61, 67, 71, 73, 79, 83, 89, 97...) in natural numbers.

SHA256 hash function:

- $\text{Ch}(x,y,z) = (x \square y) \square (\neg x \square z)$
- $\text{Ma}(x,y,z) = (x \square y) \square (x \square z) \square (y \square z)$
- $\Sigma_0(x) = S^2(x) \square S^{13}(x) \square S^{22}(x)$
- $\Sigma_1(x) = S^6(x) \square S^{11}(x) \square S^{25}(x)$
- $\sigma_0(x) = S^7(x) \square S^{18}(x) \square R^3(x)$
- $\sigma_1(x) = S^{17}(x) \square S^{19}(x) \square R^{10}(x)$

Where:

- \square : bitwise “AND”
- \neg : bitwise “Padding”
- \square : bitwise “Exclusive OR”
- S^n : Circularly shift right by n bits
- R^n : Shift right by n bits

35.3.3 Principle of GMAC

Authentication is actually a redundant message generated against the message itself, that is, the message authentication code (MAC). MAC is a technique for authenticating the integrity of a message. In cryptography, MAC refers to a verification mechanism used by both communication entities and a tool to ensure the integrity of message data. MAC is a hash function with a key. But why does it need a key? The reason is that the message can be tampered with during transmission, so can the hash value. Therefore, to ensure a valid hash value, the hash value is protected by encryption, so that the receiver can judge the integrity of the whole message through the hash value upon reception, thus completing information transfer.

The MAC process is shown as follows:

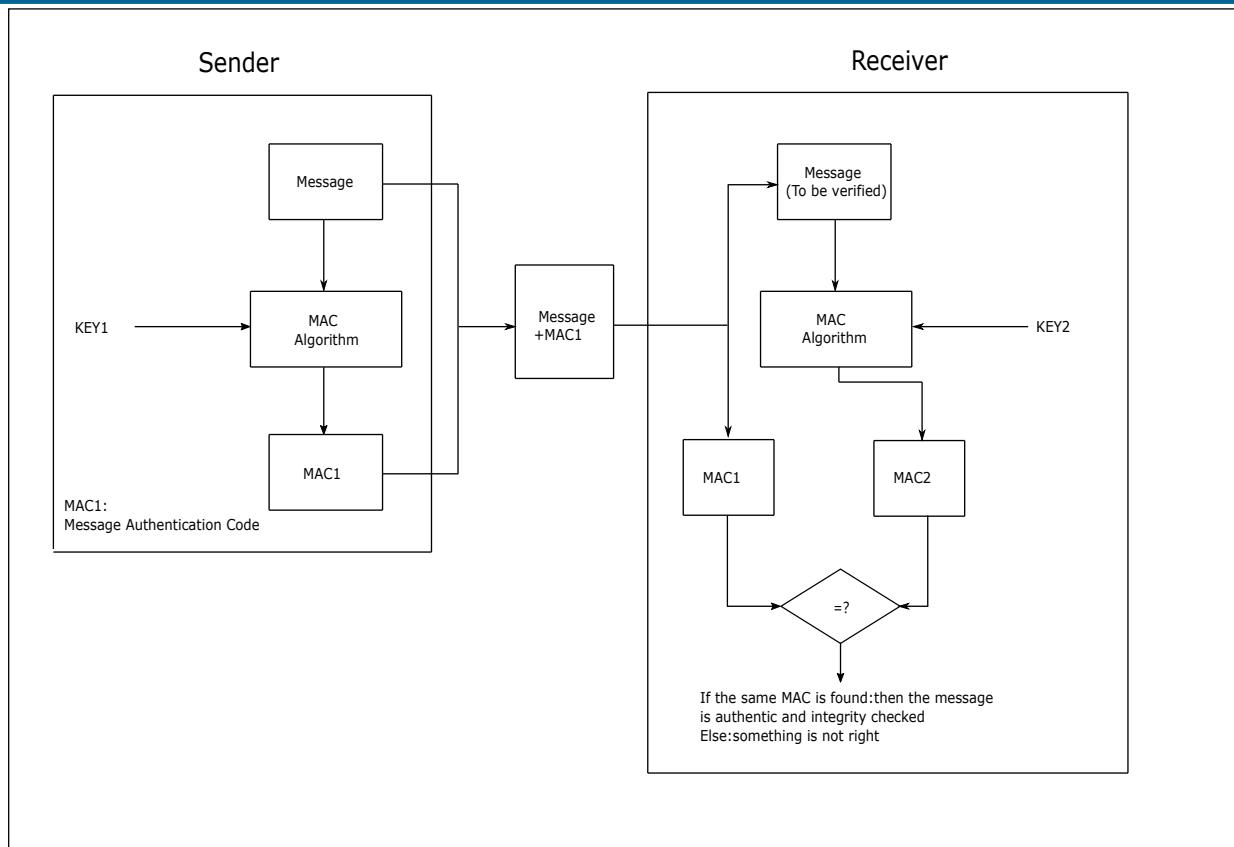

Fig. 35.3: MAC Flow Chart

1. The sender and the receiver share the key K in advance (keep KEY1 and KEY2 values in the above figure consistent).
2. The sender calculates the MAC value based on the message (KEY1 is used to calculate the MAC1 for the original message).
3. The sender sends the original message and MAC1 to the receiver.
4. The receiver calculates MAC2 using KEY2 based on the received original message .
5. The receiver compares the calculated MAC2 with the MAC1 received from the sender.
6. If the MAC is consistent, the receiver can judge that the message is indeed from the sender (authentication succeeded) and has not been tampered with or there is a transmission error. If not, the message is not from the sender (authentication failed).

Note: It is recommended that the sender and the receiver store the KEY in the hardware security module, and the MAC value also shall be calculated in that module, to ensure the security of KEY, for example, in the encrypted chip.

GMAC is to use Galois Field (GF, finite field) multiplication to calculate the MAC value of a message.

35.4 Functional Description

35.4.1 AES Accelerator

1. AES accelerator supports AES128/192/256 encryption and decryption.
- Configure se_aes_0_mode and se_aes_0_dec_en in the register se_aes_0_ctrlL, as shown below:

amode	adec en	运算
0	0	AES-128 加密
1	0	AES-256 加密
2	0	AES-192 加密
0	1	AES-128 解密
1	1	AES-256 解密
2	1	AES-192 解密

Fig. 35.4: AES Operation Modes

Configure se_aes_0_block_mode in the register se_aes_0_ctrlL to select among different encryption modes including ECB, CTR, CBC, and XTS.

2. Key, plaintext, ciphertext, and initialization vector

- The register se_aes_0_msa stores the address of plaintext or ciphertext.
- The register se_aes_0_msa stores the address of ciphertext or plaintext.
- The register se_aes_0_iv_0~se_aes_0_iv_3 stores IV.
- The register se_aes_0_key_0~se_aes_0_key_7 stores the key.

3. Software and hardware encryption process

- Configure the register se_aes_0_endian, including se_aes_0_dout_endian, se_aes_0_din_endian, se_aes_0_key_endian, se_aes_0_iv_endian, and se_aes_0_twk_endian

Note: 0: littleendian 1: bigendian

- Configure se_aes_0_block_mode in the register se_aes_0_ctrlL
- Configure se_aes_0_mode in the register se_aes_0_ctrlL
- Configure se_aes_0_dec_en in the register se_aes_0_ctrlL
- Configure se_aes_0_dec_key_sel 0:new key 1:same key as last one in the register se_aes_0_ctrlL

- Configure se_aes_0_iv_sel 0:new iv 1:same iv as last one in the register se_aes_0_ctrlL
- Configure se_aes_0_en enable aes in the register se_aes_0_ctrlL
- Configure the register se_aes_0_iv_0~se_aes_0_iv_3 set IV.

Sequence of filling: MSB: se_aes_0_iv_0~se_aes_0_iv_3; LSB: se_aes_0_iv_3~se_aes_0_iv_0

- Configure the register se_aes_0_key_0~se_aes_0_key_7 set key.

Sequence of filling: MSB: se_aes_0_key_0~se_aes_0_key_7; LSB: se_aes_0_key_7~se_aes_0_key_0.

Bits for filling: first 4 bits for AES128; first 6 bits for AES196, and first 8 bits for AES256.

- Configure the register se_aes_0_msa set msa addr
- Configure the register se_aes_0_msa set mda addr
- Configure se_aes_0_msg_len set msg len in the register se_aes_0_ctrlL
- Configure se_aes_0_trig_1t Trigger AES Engine in the register se_aes_0_ctrlL
- The output result is stored in the address corresponding to the register se_aes_0_mda

35.4.2 SHA Accelerator

- SHA accelerator supports 7 standard operations:

- SHA-1、SHA-224、SHA-256、SHA-512、SHA-384、SHA-512/224、SHA-512/256, 同时还支持 MD5、CRC16、CRC32。

The se_sha_0_mode in the register se_sha_0_ctrl: 0:SHA-256 1:SHA-224 2:SHA-1 3:SHA-1 4:SHA-512 5:SHA-384 6:SHA-512/224 7:SHA-512/256

The se_sha_0_mode_ext in the register se_sha_0_ctrl: hash mode extention; 0:SHA 1:MD5 2:CRC-16 3:CRC-32

Configure se_sha_0_mode in the register se_sha_0_ctrl to select among different SHA operations, and configure se_sha_0_mode_ext in the register se_sha_0_ctrl to select among MD5, CRC16, and CRC32

- The se_sha_0_mode is valid when se_sha_0_mode_ext is 0.
- The se_sha_0_mode is invalid when se_sha_0_mode_ext is not 0.

- Plaintext and ciphertext

- The register se_sha_0_msa stores the plaintext address.
- The register se_sha_0_hash_l_0~se_sha_0_hash_l_7 stores the ciphertext.

Sequence: MSB: se_sha_0_hash_l_0~se_sha_0_hash_l_7; LSB: se_sha_0_hash_l_7~se_sha_0_hash_l_0

- Operation flow

- Configure se_sha_0_mode set SHA operation type in the register se_sha_0_ctrl
- Configure se_sha_0_en enable sha in the register se_sha_0_ctrl
- Configure se_sha_0_hash_sel 0:new hash 1:accumulate last hash in the register se_sha_0_ctrl
- Configure the register se_sha_0_msa set mda addr
- Configure se_sha_0_msg_len set msg len in the register se_sha_0_ctrl
- Configure se_sha_0_trig_1t Trigger SHA Engine in the register se_sha_0_ctrl
- **The output result is stored in se_sha_0_hash_l_0~se_sha_0_hash_l_7 MSB:se_sha_0_hash_l_0~se_sha_0_hash_l_7 LSB:se_sha_0_hash_l_7~se_sha_0_hash_l_0**

35.4.3 Random Number Generator (RNG)

1. The random numbers generated by the built-in true RNG can be used as the basis for encryption and other operations.
 - True random numbers: They are generated through physical phenomena, such as coin tossup, dicing, wheel rotation, noise from using electronic components, and nuclear fission. Such RNGs are called physical RNGs, and their weaknesses are high technical requirements.
 - Pseudo-random numbers: Truly random numbers (or random events) are randomly generated in a generation process according to the distribution probability shown in the experimental process, and the result is unpredictable and invisible. The random function in the computer is simulated according to a specified algorithm, and its result is deterministic and visible. We can think that the probability of this foreseeable result is 100%. Hence the “random number” generated by computer random function is not truly random, but pseudo-random.
2. Output
 - The register SE_TRNG_0_DOUT_0~SE_TRNG_0_DOUT_7 stores the output random number.
3. Usage process
 - Configure se_trng_0_en enable trng in the register se_trng_0_ctrl_0
 - Configure se_trng_0_trig_1t trigger trng engine in the register se_trng_0_ctrl_0
 - The output result is stored in se_trng_0_dout_0~se_trng_0_dout_7

35.4.4 GMAC(link Mode)

1. Definition of GMAC_link_Table Structure

- Word0:
 - [9]:se_gmac_0_int_clr_1t
 - [10]:se_gmac_0_int_set_1t
 - [31:16]:se_gmac_0_msg_len
- Word1:se_gmac_0_msa
- Word2、Word3、Word4、Word5: se_gmac_0_h
- Word6、Word7、Word8、Word9: se_gmac_0_tag

2. Usage process

- Configure se_gmac_0_x_endian, se_gmac_0_h_endian, and se_gmac_0_t_endian 0:littleendian 1:bigendian in the register se_gmac_0_ctrl_0
- Write the start address of the GMAC_link_Table structure into the register se_gmac_0_lca
- Assign the original message address to se_gmac_0_msa in Word1 in GMAC_link_Table structure
- Assign the original message length to se_gmac_0_msg_len in Word0 in GMAC_link_Table structure, where the 128-bit message length corresponds to 1 in se_gmac_0_msg_len
- Configure se_gmac_0_trig_1t trigger gmac engine in the register se_gmac_0_ctrl_0
- The output result is stored in Word6~Word9 in the GMAC_link_Table structure
